LIST OF SYMBOLS

<u>Symbol</u>	<u>Definition</u>
$C_{P_{\text{mean}}}$	Mean pressure coefficient, $\frac{(p-p_{\infty})_{\text{mean}}}{q}$
$C_{P_{\text{rms}}}$	Root-mean-square pressure coefficient, $\frac{\left((p-p_{\infty})-(p-p_{\infty})_{\text{mean}}\right)_{\text{rms}}}{q}$
$C_{P_{\text{max}}}$	Peak maximum pressure coefficient, $\frac{(p-p_{\infty})_{\text{max}}}{q}$
$C_{P_{\text{min}}}$	Peak minimum pressure coefficient, $\frac{(p-p_{\infty})_{\text{min}}}{q}$
$( )_{\text{min}}$	Minimum value during data record
$( )_{\text{max}}$	Maximum value during data record
D	Characteristic dimension (building height, width, etc.)
E	Mean voltage
$E_{\text{rms}}$	Root-mean-square of fluctuating voltage
$f_o$	Natural cyclic frequency, Hz
g	Peak factor, $= (\hat{M} - \bar{M})/\sigma_M$
I	Moment of inertia
$k^*$	Generalized stiffness
$k_{\theta}$	Rotational stiffness
$m^*$	Generalized mass
$m_i$	Lumped mass at floor i
M	Resultant base moment of applied wind load
$\bar{M}$	Response (static equivalent) base moment
$\bar{M}, M', \hat{M}$	Mean, fluctuating, and expected peak values of M
p	Pressure

<u>Symbol</u>	<u>Definition</u>
$p_{\infty}$	Static pressure in wind tunnel above model
$p^*$	Generalized load
$P_i$	Resultant force of applied wind load acting at floor $i$
$\bar{P}_i$	Response (static equivalent) force acting at floor $i$
$\bar{P}_i, P_i', \hat{P}_i$	Mean, fluctuating, and expected peak values of $P_i$
$q$	Reference dynamic pressure, $\rho U_{\infty}^2/2$
$S_{( )}(f)$	Power spectral density of ( )
$T_u$	Turbulence intensity $\frac{U_{rms}}{U}$
$U$	Local mean velocity
$U_{\infty}$	Reference mean velocity outside the boundary layer
$U_{rms}$	Root-mean-square of fluctuating velocity
$x, y$	Horizontal coordinates
$z$	Height above surface
$z_i$	Height of floor $i$
$\delta$	Height of boundary layer
$\Delta_i$	Lateral displacement of floor $i$
$\bar{\Delta}_i, \Delta_i', \hat{\Delta}_i$	Mean, fluctuating, and expected peak values of $\Delta_i$
$\nu$	Kinematic viscosity of approach flow
$\rho$	Density of approach flow
$\sigma_M$	Standard deviation of $M, = M'_{rms}$
$\sigma_i$	Standard deviation of $P_i, = (P_i')_{rms}$
$\sigma_{\Delta i}$	Standard deviation of $\Delta_i, = (\Delta_i')_{rms}$
$\theta$	Rotation of a straight line approximating the building displacement

<u>Symbol</u>	<u>Definition</u>
$\theta'$	Fluctuating rotation, approximates the generalized coordinate $\xi$
$\phi$	Modal deflection
$\zeta$	Critical damping ratio
$\xi$	Generalized response

## 1. INTRODUCTION

### 1.1 General

Wind effects on the International Place building complex have been defined in a series of three reports. The first two reports [1, 2] involved a flow visualization study of pedestrian winds [1] and a quantitative analysis of pedestrian wind comfort in which wind speeds of numerous pedestrian locations were compared to Boston city acceptability criteria [2]. This report is the third in the series which defines the Phase 1 tower and low-rise wind loads for cladding elements and structural loads for the building frame which includes the dynamic properties of the building.

A significant characteristic of modern building design is lighter cladding and more flexible frames. These features produce an increased vulnerability of glass and cladding to wind damage and result in larger deflections of the building frame. The building geometry itself may substantially influence the wind loading on the structure. Wind forces may be modified by nearby structures which can produce beneficial shielding or adverse increases in loading. Overestimating loads results in uneconomical design; underestimating may result in cladding or glazing failures. In flexible structures, wind-induced motion may cause occupant discomfort if not anticipated during the design phase.

Techniques have been developed for wind-tunnel modeling of proposed structures which allow the prediction of wind pressures on cladding, windows, overall structural loading, and also wind velocities and gusts in pedestrian areas adjacent to the building. Accurate knowledge of the intensity and distribution of the pressures on the structure permits adequate but economical selection of cladding strength to meet selected

maximum design winds and overall wind loads for the design of the frame for flexural control.

Modeling of the aerodynamic loading on a structure requires special consideration of flow conditions in order to guarantee similitude between model and prototype. A detailed discussion of the similarity requirements and their wind-tunnel implementation can be found in references [3], [4], and [5]. In general, the requirements are that the model and prototype be geometrically similar, that the approach mean velocity at the building site have a vertical profile shape similar to the full-scale flow, that the turbulence characteristics of the flows be similar, and that the Reynolds number for the model and prototype be equal.

These criteria are satisfied by constructing a scale model of the structure and its surroundings and performing the wind tests in a wind tunnel specifically designed to model atmospheric boundary-layer flows. Reynolds number similarity requires that the quantity  $UD/\nu$  be similar for model and prototype. Since  $\nu$ , the kinematic viscosity of air, is identical for both, Reynolds numbers cannot be made equal with reasonable wind velocities. To accomplish this the air velocity in the wind tunnel would have to be as large as the model scale factor times the prototype wind velocity, a velocity which would introduce unacceptable compressibility effects. However, for sufficiently high Reynolds numbers ( $>2 \times 10^4$ ) the pressure coefficient at any location on the structure will be essentially constant for a large range of Reynolds numbers. Typical values encountered are  $10^7$ - $10^8$  for the full-scale and  $10^5$ - $10^6$  for the wind-tunnel model. In this range acceptable flow similarity is achieved without precise Reynolds number equality.

Modeling of the building's dynamic response required that dynamic tests of the structure be performed. A three degrees-of-freedom model was assumed and scaled for the wind-tunnel conditions. Requirements for similarity between model and full-scale building for these models are discussed in references [5, 6]. For the dynamic tests, a rigid model was elastically supported by springs at its base. The springs permitted rotation of the model around two orthogonal axes located in the horizontal plane, and about a vertical axis. The natural frequencies of the three degrees of freedom of the model were significantly higher than the frequencies in the aerodynamic loading spectrum of the wind-induced forces. This enabled direct measurement of the fluctuating wind loads on the building. Mathematical computation using dynamic properties of the full-scale building in combination with wind-tunnel measurements of loading spectra allowed the building response to be determined.

## 1.2 The Wind-Tunnel Test

The wind engineering study was performed on the International Place building group modeled at a scale of 1:384. A rigid building model of the Phase I tower and low-rise structure for pressure data acquisition was constructed of clear plastic fastened together with screws. The structure was modeled in detail to provide accurate flow patterns in the wind passing over the building surfaces. To achieve similarity in wind effects, the area surrounding the test building was also modeled including the Phase II tower. The Phase II tower was removable so that data on Phase I could be obtained with and without Phase II. A flow visualization study was made (using smoke to make the air currents visible) to define overall flow patterns and identify regions where local flow features might cause high pressures on the curtain-wall.

The pressure test models, equipped with pressure or "piezometer" taps, were exposed to an appropriately modeled atmospheric wind in the wind tunnel and the fluctuating pressure at each tap was measured electronically. The model, and the modeled area, were rotated 10 degrees and another set of data recorded for each pressure tap. The entire 360-degree range was covered at 10-degree intervals.

Data were recorded, analyzed and processed by an on-line computerized data-acquisition system. Pressure coefficients of several types were calculated by the computer for each reading on each piezometer tap and were printed in tabular form as computer readout. Using wind data applicable to the building site, representative wind velocities were selected for combination with measured pressures on the building model. Integration of test data with wind data resulted in prediction of peak local wind pressures for design of glass or cladding. Overall mean forces and moments on the structure were obtained by integrating the mean pressures over the building's surface. Pressure contours were drawn on the developed building surfaces showing the intensity and distribution of peak wind loads on the building. These results may be used to divide the building into zones where lighter or heavier cladding or glass may be desirable.

The dynamic response of the building was evaluated using the dynamic model, which was instrumented to sense base moments. These measurements were made for each of 36 wind directions to determine building response sensitivity to different wind directions. Measurements were made with and without the Phase II tower in place. The dynamic load information obtained by the dynamic model was combined with structural characteristics of the tower provided by the sponsor to

predict building dynamic response, including response base moments and top floor accelerations.

The following pages discuss in greater detail the procedures followed and the equipment and data collecting and processing methods used. In addition, the data presentation format is explained and the implications of the data are discussed.

## 2. EXPERIMENTAL CONFIGURATION

### 2.1 Wind Tunnel

Wind engineering studies are performed in the Fluid Dynamics and Diffusion Laboratory at Colorado State University (Figure 1). Three large wind tunnels are available for wind loading studies depending on the detailed requirements of the study. The wind tunnel used for this investigation is shown in Figure 2. The tunnel has a flexible roof adjustable in height to maintain a zero pressure gradient along the test section. The mean velocity can be adjusted continuously in the tunnel to the maximum velocity available.

### 2.2 Pressure Model

In order to obtain an accurate assessment of local pressures using piezometer taps, models are constructed to the largest scale that does not produce significant blockage in the wind-tunnel test section. The models were constructed of 1/2-in. (1.3 cm) thick acrylic plastic and fastened together with metal screws. Significant variations in the building surface were machined into the plastic. Piezometer taps (1/16 in. (1.6 mm) diameter) were drilled normal to the exterior vertical surfaces in rows at a number of elevations between the bottom and top of the building. Similarly, taps were placed in the roof and on

sloping, protruding, or otherwise distinctive features of the building that might need investigation.

Pressure tap locations were chosen so that the entire surface of the building could be investigated for pressure loading and at the same time permit critical examination of areas where experience has shown that maximum wind effects may be expected to occur. Locations of the pressure taps for this study are shown in Figure 3. Dimensions are given both for full-scale building (in ft) and for model (in in.). The pressure tap numbers are shown adjacent to the taps.

The pressure tests are sometimes made in two stages. In the first stage, measurements are made on the initial distribution of pressure taps. If it becomes apparent from the data that the loading on the building is being influenced by some unsuspected geometry of the building or adjacent structures, additional pressure taps are installed in the critical areas. The locations of the taps are selected so that the maximum loading can be detected and the area over which this loading is acting can be defined. Any added taps are also shown in Figure 3.

Photographs of the pressure model installed in the wind tunnel are shown in Figure 4.

### 2.3 Dynamic Model

The dynamic model was designed to study the dynamic response of the fundamental mode of vibration of a tower in three independent components: translation in two orthogonal directions, and rotation about a vertical axis. To accomplish this, in each component the structure is reduced to an equivalent single-degree-of-freedom (SDOF) system using the modal analysis technique of generalized coordinates. This procedure is described in Appendix C. The equivalent SDOF system is characterized

by a generalized mass  $m^*$ , generalized stiffness  $k^*$ , generalized load  $p^*$ , and generalized response  $\xi$ . A linear mode shape is assumed, for which the test models used represent an exact analogy. For this case, it is shown in Appendix C that the corresponding model properties to the above generalized values are mass moment of inertia  $I$ , rotational stiffness  $k_\theta$ , externally-applied base moment  $M$ , and axis rotation  $\theta$ .

The dynamic properties of generalized mass, generalized stiffness, and natural frequency assumed in this study are given in Table 4. (The coordinate system is defined in Figure 5.) The natural frequency  $f_0$  and mass distribution  $[m]$  were specified by McNamara/Salvia structural engineers. The generalized mass  $m^*$ , or moment of inertia  $I$ , was calculated using Equation (C.4). The generalized stiffness  $k^*$ , or rotational stiffness  $k_\theta$  was then calculated using Equation (C.3).

The construction of the dynamic model and balance system is shown in Figure 6. The model was built up of aluminum and architectural styrofoam and mounted on a 1 1/2-in. diameter steel tube. The tube was bolted to the balance plate as shown, and provided the high rigidity required to respond as an SDOF system at a high natural frequency. The balance plate was connected to a heavy steel reaction ring via necked-down sections of steel crossbeams. These "springs" deform in both the horizontal and vertical planes, and thus provide three components of motion-rotation about the x, y, and z axes shown.

The spring elements in the balance fixtures for the dynamic model (see Figure 6) were instrumented with strain gages to sense the rotation of the model. The spring deformations are very small, so semiconductor gages (BLH-type SPB3-07-35), which have a much higher sensitivity than standard foil gages, were used.

The strain gages were formed into three bridge networks--one for each of the three degrees-of-freedom of the building motion. These bridges were conditioned and monitored by Honeywell Accudata 218 Gage Control/Amplifier units which provided excitation to the bridge and amplification of the bridge output. These signals were processed through an on-line data-acquisition system. The output signal was converted to a moment value using the results of a static calibration of the balance.

During test runs data were taken at a sample rate of about 200 samples per second on each channel. The sample duration time was selected on the basis of repeatability of sampling runs made early in the testing phase, and corresponds to about 1 hour at full scale. The data were processed immediately to determine mean, rms, and peak loads. The data were also stored on digital tape for further analysis.

The dynamic balance was instrumented with strain gages to measure the base moment  $M$ , or generalized load  $p^*$ , about these three axes. Scaling was accomplished by expressing this load as a moment coefficient, defined as

$$C_M = \frac{M}{q A L}$$

where  $q$  is the dynamic reference pressure  $\rho U_\infty^2/2$ ,  $A$  is a reference area, and  $L$  is a characteristic reference length such as the height of the building. Measured coefficients are applicable to both the model and prototype.

Once the generalized load is determined, its power spectral density  $S_M(f)$  is computed (Appendix C). The fluctuating mean square of the response base moment can then be computed by combining equations (C.7) and (C.9):

$$\sigma_M^2 = \int_0^{\infty} S_M(f) df = \int_0^{\infty} |H(f)|^2 S_M(f) df$$

All of the essential dynamic properties of the building are incorporated in  $|H(f)|^2$ , the mechanical admittance:

$$|H(f)|^2 = \frac{1}{[1-(f/f_0)^2]^2 + (2\zeta f/f_0)^2}$$

where  $f_0$  is the natural frequency, and  $\zeta$  is the critical damping ratio.

An accepted procedure in the present context is to use the so-called white noise approximation; then

$$\sigma_M^2 = S_M(f_0) \int_0^{\infty} |H(f)|^2 df$$

This integration can be performed analytically, with the result

$$\sigma_M^2 = \frac{\pi}{4\zeta} f_0 S_M(f_0) \quad (5)$$

The square root of this is the desired rms dynamic response  $\sigma_M$ . Note that any value of natural frequency  $f_0$  and damping ratio  $\zeta$  may be incorporated after the test results,  $S_M(f)$ , are obtained.

#### 2.4 Model Environment

A circular area 1800 ft in radius surrounding the building was modeled in detail. Structures within the modeled region were made from styrofoam and cut to the individual building geometries. The model and its surroundings were mounted on a turntable (Figure 2) near the downwind end of the test section. Any significant buildings or terrain features which did not fit on the turntable were placed on removable pieces and placed upwind of the turntable for appropriate wind directions. A plan view of the building and its surroundings is shown in Figure 7. This environment was used for the pressure model and the dynamic model.

The region upstream from the modeled area was covered with a randomized roughness constructed using various sized cubes placed on the floor of the wind tunnel. Spires were installed at the test-section entrance to provide a thicker boundary layer than would otherwise be available. The thicker boundary layer permitted a somewhat larger scale model than would otherwise be possible. The spires were approximately triangularly-shaped pieces of 1/2-in. thick plywood 6 in. wide at the base and 1 in. wide at the top, extending from the floor to the top of the test section. They were placed so that the broad side intercepted the flow. A barrier approximately 8 in. high was placed on the test-section floor downstream of the spires to aid in development of the boundary-layer flow.

The distribution of the roughness cubes and the spires in the roughened area was designed to provide a boundary-layer thickness of approximately 4 ft, and a velocity profile power-law exponent similar to that expected to occur in the region approaching the modeled area for each wind direction. Photographs of the completed pressure model in the wind tunnel are shown in Figure 4. The wind-tunnel ceiling was adjusted after placement of the model to obtain a zero pressure gradient along the test section.

### 3. INSTRUMENTATION AND DATA ACQUISITION

#### 3.1 Flow Visualization

Making the air flow visible in the vicinity of the model is helpful

- (a) in understanding and interpreting mean and fluctuating pressures,
- (b) in defining zones of separated flow and reattachment and zones of vortex formation where pressure coefficients may be expected to be high,

(c) in interpretation of building dynamic response. Titanium tetrachloride smoke was released from sources on and near the model to make the flow lines visible to the eye and to make it possible to obtain motion picture records of the tests. Conclusions obtained from these smoke studies are discussed in Section 4.1.

### 3.2 Wind Velocity

Mean velocity and turbulence intensity profiles were measured upstream of the model, using a hot-film anemometer, to confirm that approach boundary-layer flows, established in the second part of this study [2], had been established. Velocity measurement procedures were outlined in [2] and are not repeated here. Profiles of mean velocity and turbulence intensity approaching the model and at the project site in the preconstruction configuration are shown in Figure 9. The approach velocity profiles are quite close to those used in the pedestrian velocity study.

### 3.3 Pressures

Mean and fluctuating pressures were measured at each of the pressure taps on the model structure. Data were obtained for 36 wind directions, rotating the entire model assembly in a complete circle. Up to 184 pieces of 1/16 in. I.D. plastic tubing were used to connect 184 pressure ports at a time to four 48-tap pressure switches mounted underneath the model. The switches were designed to minimize the attenuation of pressure fluctuation across the switch. Each of the 184 measurement ports was directed in turn by the switch to one of four pressure transducers mounted close to the switch. Four pressure input ports not used for transmitting building surface pressures were connected to a common tube leading to a pitot tube mounted inside the wind

tunnel which provided a means of automatically monitoring the tunnel speed. The switch was operated under control of the data acquisition system. The other four input ports were used for monitoring of the transducer zero.

The pressure transducers used were Setra differential transducers (Model 237) with a 0.10 psid (690 Pad) range. Reference pressures were obtained by connecting the reference sides of the four transducers, using plastic tubing, to the static side of a pitot-static tube mounted in the wind-tunnel free stream above the model building. In this way the transducer measured the instantaneous difference between the local pressures on the surface of the building and the static pressure in the free stream above the model.

Output from the pressure transducers was fed to an on-line data acquisition system consisting of a Hewlett-Packard 21 MX computer, disc unit, card reader, printer, Digi-Data digital tape drive and a Preston Scientific analog-to-digital converter. The data were processed immediately into pressure coefficient form as described below and stored for printout or further analysis.

All four transducers were recorded simultaneously for 16 seconds at a 250 sample-per-second rate. The results of an experiment to determine the length of record required to obtain stable mean and rms (root-mean-square) pressures and to determine the overall accuracy of the pressure data acquisition system is shown in Figure 8. A typical pressure port record was integrated for a number of different time periods to obtain the data shown. Examination of a large number of pressure taps showed that the overall accuracy for a 16-second period is, in pressure coefficient form, 0.03 for mean pressures, 0.1 for peak pressures, and 0.01 for rms pressures. Pressure coefficients are defined below.

For each of the pressure taps examined at each wind direction, the data record was analyzed to obtain four separate pressure coefficients. The first is the mean pressure coefficient

$$C_{p_{\text{mean}}} = \frac{(p-p_{\infty})_{\text{mean}}}{q}$$

It represents the mean of the instantaneous pressure difference between the building pressure tap and the static pressure in the wind tunnel above the building model, nondimensionalized by the dynamic pressure

$$q = \rho U_{\infty}^2 / 2$$

at the reference velocity position. This relationship produces a dimensionless coefficient which indicates that the mean pressure difference between building and ambient wind at a given point on the structure is some fraction less or some fraction greater than the undisturbed wind dynamic pressure near the upper edge of the boundary layer. Using the measured coefficient, prototype mean pressure values for any wind velocity may be calculated.

The magnitude of the fluctuating pressure is obtained by the rms pressure coefficient

$$C_{p_{\text{rms}}} = \frac{\left( (p-p_{\infty}) - (p-p_{\infty})_{\text{mean}} \right)_{\text{rms}}}{q}$$

in which the numerator is the root-mean-square of the instantaneous pressure difference about the mean.

If the pressure fluctuations followed a Gaussian probability distribution, no additional data would be required to predict the frequency with which any given pressure level would be observed. However, the pressure fluctuations do not, in general, follow a Gaussian probability distribution so that additional information is required to show

the extreme values of pressure expected. The peak maximum and peak minimum pressure coefficients are used to determine these values:

$$C_{P_{\max}} = \frac{(p-p_{\infty})_{\max}}{q}$$

$$C_{P_{\min}} = \frac{(p-p_{\infty})_{\min}}{q}$$

The values of  $p-p_{\infty}$  which were digitized at 250 samples per second for 16 seconds, representing about one hour of time in the full-scale, are examined individually by the computer to obtain the most positive and most negative values during the 16-second period. These are converted to  $C_{P_{\max}}$  and  $C_{P_{\min}}$  by nondimensionalizing with the free stream dynamic pressure.

The four pressure coefficients are calculated by the on-line data acquisition system computer and tabulated along with the approach wind azimuth in degrees from true north. The list of coefficients is included as Appendix A. The pressure tap code numbers used in the appendix are explained in Figure 3.

To determine the largest peak loads acting at any point on the structure for cladding design purposes, the pressure coefficients for all wind directions were searched to obtain, at each apressure tap, the largest value of peak pressure coefficient. Table 2 provides these pressure coefficients and associated wind directions. Included in Section 4.2 is an analysis of the coefficients of Table 2 including the maximum values obtained and where they occurred on the building.

The pressure coefficients of Table 2 can be converted to full-scale loads by multiplication by a suitable reference pressure,  $q$ , selected for the field site. This value is the dynamic pressure associated with

an hourly mean wind at the reference velocity measurement position at the edge of the boundary layer. In general, the method of arriving at a design reference pressure for a particular site involves selection of a design wind velocity, translation of the velocity to an hourly mean wind at the reference velocity location and conversion to a reference pressure. Selection of the design velocity can be made from statistical analysis of extreme wind data. The calculation of reference pressure for this study is shown in Table 1. The factor used in Table 1 to reduce gust winds to hourly mean winds is given in reference [8].

The reference pressure associated with the design hourly mean velocity at the reference velocity location can be used directly with the peak-pressure coefficients to obtain peak local design wind loads for cladding design. Local, instantaneous peak loads on the full-scale building suitable for cladding design were computed by multiplying the reference pressure of Table 1 by the peak coefficients of Table 2 and are listed as peak pressure in that table. The maximum psf load given at each tap location is the absolute value of the maximum value found in the tests, irrespective of its algebraic sign. For ease in visualizing the loads on the structure, contours of equal peak pressures for cladding loads shown in Table 2 have been plotted on developed elevation views of the structure, Figure 10. For control of water infiltration from outside to inside, the largest positive (inward-acting) pressure of each tap location is tabulated in Table 2.

For glass design pressures, a glass load factor is used to account for the different duration between measured peak pressures and the one-minute loading commonly used in glass design charts. The design pressure used for glass is normally less than the peak pressures used

for cladding design because of the static fatigue property of glass which can withstand higher pressures for short duration loads than for long duration loads. Research [9] indicates that the period of application of the peak pressures reported herein is about 5-10 seconds or less. If a glass design is based on these peak-pressure values, then a glass strength associated with this duration load should be used. Because glass design charts are normally based on some alternate load duration--usually one minute--then some reduction in peak loads should be made. An estimate of a load reduction factor can be obtained from an empirical relation of glass strength as a function of load duration. Current glass selection charts showing glass strength as a function of load duration [10] and older references [11] indicate the following load reduction factors:

	ref. 10	ref. 11
annealed float	0.80	0.81
heat strengthened	0.94	
tempered	0.97	0.98

Loadings appropriate for glass design can be computed by multiplying the peak-pressure loads of Table 2 by these load factors.

### 3.4 Mean Forces and Moments

Since the mean load on a structure is independent of its dynamic response, and therefore of any time scale in the model, measured mean values may be scaled to the prototype in the same manner as pressures. Thus if the mean pressure distribution is determined as described in the preceding section, the associated force acting on any part of the structure may be determined by integration. This has been done in a manner which results in the mean force acting at each floor level in the x and y directions, and the resultant torque about the z axis.

The mean forces and torques obtained at each floor were used to obtain load, shear, and moment diagrams for the building for each wind direction, Table 3. The shear diagram was obtained by algebraic sum of all forces in each coordinate direction acting above the floor of interest. The load diagram was obtained by dividing the forces by their contributing areas (listed in Table 3). Eccentricities were computed such that the product of the y force and x eccentricity minus the product of the x force and y eccentricity equaled the torque at that floor. The moment diagram, in 1000 kip-ft, was obtained by integration of the shear values so that the moment due to forces acting above the floor level of interest was calculated. The sign of the moment was established by the right-hand rule about an x', y' axis through the floor of interest. Moments about the z axis were calculated by summing the torques acting on all floors above the floor level of interest. Load, shear, and moment diagrams are shown in Figure 11 for several wind directions.

Mean base moments are also available from the dynamic model test results, as described in Section 2.3. A comparison is made of mean base moments from both methods in Figure 12, which shows the x, y, and z base moments plotted as a function of wind direction.

### 3.5 Total Base Moments

This section presents the results of dynamic model tests. As described in Section 2.3, the moment at the base of the structure is treated as the fundamental response parameter. The "total" base moment is the sum of the mean and fluctuating parts. In particular, the test results will be analyzed in terms of the maximum (or minimum) expected peak response. Section 3.6 will describe how these results may be used

to estimate the distribution of equivalent static loads at each floor level.

The peak response base moment for a given wind direction  $\alpha$  is directly measurable from the aeroelastic model test run. It can be expressed as (see Equation (C.10))

$$\hat{M}(\alpha) = \bar{M}(\alpha) + g\sigma_M(\alpha)$$

where  $\hat{M}$ ,  $\bar{M}$ , and  $\sigma_M$  are observed peak, mean, and fluctuating rms values, respectively, of the base moment determined by procedures described above. The "peak factor"  $g$  was determined from Equation (C.11), and  $\sigma_M$  was computed according to equation (5).

Peak base moments  $\hat{M}$  were calculated for each degree of freedom at each wind direction. The results are given in Figure 13. The wind velocity for these results corresponds to the 100-year mean recurrence interval conditions described in Table 1. The damping ratio in the structure,  $\zeta$ , was assumed to be .01 (1 percent of critical) or .015. The peak factors  $g$  are indicated as "PF." The peak values shown may be interpreted as "the expected value of the largest peak excursion in (static equivalent) response base moment occurring in a 1-hour period during the wind storm which occurs, on the average, every 100 years."

### 3.6 Force Distribution with Height

If the total response (or static equivalent) force acting at the  $i$ th floor is expressed as the sum of a mean and a fluctuating component, i.e.,

$$P_i = P_i + P'_i$$

then, in a manner analogous to that used for the base moment in the previous section, the peak expected force may be written

$$\hat{p}_i = \bar{p}_i + g \sigma_{p_i} \quad (3.1)$$

where  $g$  is the same peak factor which was determined for the base moment. The distribution of the mean forces  $\bar{p}_i$  (which are the same as  $P_i$ ) was discussed in Section 3.4, and the results appear in Table 3. In this section a means of estimating the rms fluctuating forces  $\sigma_{p_i}$  will be described. Reference is made to Appendix C concerning modal analysis concepts.

Since the structure's motion is essentially in a normal mode, the fluctuating equivalent static load at floor  $i$  is proportional to the mass and the modal deflection at that floor. If the modal deflection  $\phi_i$  is approximated by the straight line  $z_i$ , then this force may be written

$$P'_i = \alpha m_i z_i$$

These forces can be related to the base moment  $M'$ , since

$$M' = \sum P'_i z_i .$$

Substituting for  $P'_i$  leads to

$$M' = \alpha \sum m_i z_i^2 = \alpha m^*$$

where  $m^*$  is the generalized mass (see Table 4). This allows the proportionality constant  $\alpha$  to be evaluated, and the equation above for  $P'_i$  becomes

$$P'_i = \frac{M'}{m^*} m_i z_i$$

This equation shows that the individual fluctuating floor loads,  $P'_i$ , may be determined from the fluctuating base moment,  $M'$ . The rms forces can now be expressed as

$$\sigma_{P_i} = \frac{m_i z_i}{m^*} \sigma_M \quad (3.2)$$

A simpler approximation may be obtained by assuming that the mode shape  $\phi_i$  approximates the static deflected shape. In this case the above analysis applies to the total response, not just the fluctuating part, so that  $P_i$  and  $M$  can be substituted for  $P_i'$  and  $M'$ . The expected peak forces then become

$$\hat{P}_i \cong \frac{m_i z_i}{m^*} \hat{M} \quad (3.3)$$

The expected peak base moment  $\hat{M}$  may be read directly from Figure 13.

This approximation may not be good for wind directions where the mean response is a large fraction of the peak response, depending on how much the static deflected shape deviates from a straight line. Note, however, that in many cases the largest response occurs in the cross-wind direction, where the mean response is very small; in these cases the approximation is excellent.

### 3.7 Displacement and Acceleration

Displacements of the tower may be treated in a manner analogous to the analysis of forces in the preceding section. Thus the peak expected lateral deflection at floor  $i$  is

$$\hat{\Delta}_i = \Delta_i + g\sigma_{\Delta} \quad (3.4)$$

where  $\Delta$  is the mean static deflection,  $\sigma_{\Delta}$  is the fluctuating rms deflection, and  $g$  is the peak factor introduced above. The mean displacements can be obtained from a static analysis of the structural frame under the applied loads  $P_i$  (see Section 2.3). The dynamic displacements are obtained from Equation (C.2),

$$\Delta'_i = \theta' \phi_i$$

where  $\theta'$  is the fluctuating rotation of the approximate straight-line mode shape of the structure (thus  $\theta'$  approximates the generalized coordinate  $\xi$ ). By Appendix C,

$$\theta' = \frac{M'}{k_\theta}$$

Combining these equations and taking the rms value results in

$$g\sigma_{\Delta_i} = \frac{1}{k_\theta} g\sigma_M z_i \quad (3.5)$$

where  $z_i$  is taken as an approximation to the actual shape  $\phi_i$ . The rotational stiffness  $k_\theta$  is given in Table 4, and the value  $g\sigma_M$  may be read from Figure 13.

In the preceding section regarding force distributions, a simplifying assumption was made that the static deflected shape can be approximated by a straight line. This led to the simple equation (3.3) for the peak expected force. Parallel treatment of the displacements leads to

$$\hat{\Delta}_i = \frac{z_i}{k_\theta} \hat{M} \quad (3.6)$$

and 
$$\theta = \frac{M}{k_\theta}$$

The value  $\hat{M}$  may be read directly from Figure 13. Note again that the accuracy of this approximation depends on how well the deflected shape can be fit by a straight line, and on the relative contributions of mean and fluctuating response to the total response. The equation is quite accurate for the cross-wind response, for example, where the mean response is small.

Note also that the rotation  $\theta$  is essentially the so-called "drift ratio." The expected peak value of this is

$$\hat{\theta} = \frac{\hat{M}}{k_{\theta}}$$

Using the proportionality constant  $1/k_{\theta}$  from Table 4, an accessory scale for  $\theta$  can be drawn directly on Figure 13.

Due to the high degree of resonance in the dynamic response of the towers, the displacement can be written in the general functional form

$$x(t) = X \sin \omega_0 t$$

where  $\omega_0 = 2\pi f_0$  is the natural circular frequency. Differentiating this equation twice yields the following expression for acceleration:

$$\ddot{x}(t) = -\omega_0^2 \sin \omega_0 t = -\omega_0^2 x(t)$$

The root-mean-square acceleration may therefore be calculated as

$$\sigma_{\ddot{x}} = \omega_0^2 \sigma_x$$

In a similar manner,  $\sigma_{\ddot{y}}$  and  $\sigma_{\ddot{\theta}}$  can be calculated. The rotational acceleration  $\ddot{\theta}$  is converted to a tangential acceleration at a representative point located at the corner of the top floor, at distance  $r$  from the z-axis:

$$\sigma_{r\ddot{\theta}} = r\sigma_{\ddot{\theta}}$$

The values  $\sigma_{\ddot{x}}$ ,  $\sigma_{\ddot{y}}$ , and  $\sigma_{r\ddot{\theta}}$  can then be combined using Equation (B.3) to obtain a characteristic total rms acceleration of the top floor.

Using this technique, the dynamic balance data have been converted to rms accelerations for two damping ratios. These are presented in Figure 14, along with some criteria describing human response to motion in tall buildings. This issue is discussed further in Section 4.4.

## 4. DISCUSSION

### 4.1 Flow Visualization

Smoke was used to make wind flow lines visible. The smoke flow patterns showed that the largest pressures on the Phase I tower would most likely be at corners on the circular tower where changes of geometry occurred. Significant changes in geometry which could lead to elevated local cladding pressures were at the edges of the vertical notch on the northeast corner of the tower and at points of intersection of the tops of the north wing and west wing with the tower. At these locations, flow separation was observed with characteristics favorable for formation of elevated pressures.

Flow separation occurs when wind is unable to turn abruptly a corner on the building due to its inertia and flows out away (separating) from the building surface at the corner. When flow separation occurs with a high wind velocity near the corner and with a large curvature in the flow lines, then large fluctuating pressures can occur near the point of separation. It is this phenomenon which caused high local pressures on the Phase I tower.

### 4.2 Pressures

Table 2 shows the largest peak pressure coefficients and corresponding loads measured on the building for each pressure tap location. Data identified as Configuration A represent data obtained at all pressure tap locations on the Phase I building without the Phase II building in place for 36 wind directions. Configuration B represents data obtained at all taps on the Phase I with Phase II in place. Configurations C and D in Appendix A represent data obtained at selected taps at 2-degree azimuthal increments near azimuths where large pressure

peaks were observed in Configurations A and B to ensure that the largest peaks were obtained.

Peak pressures were combined with the 100-year recurrence wind including directional variations to obtain peak pressures for design purposes. The largest peak pressures measured on the Phase I building for either the A or B configurations (labeled worst case) were slightly above 70 psf at tap locations 319, 946 and 308. Taps 319 and 308 are located where flow visualization indicated flow patterns which had the possibility for elevated pressures. Tap 946 is on the roof. The distribution of peak pressures on the Phase I building is shown in Figure 10. Most of the surface area of the building had peak negative pressures in the -30 to -50 psf range with isolated areas extending up to -74 psf. Peak positive pressures were in the 10 to 35 psf range with a few locations as high as 40 psf. The largest peak pressures were not particularly large for a building of this height.

The pressures shown in this report are external wind loads and do not include internal pressures. Internal pressures are usually ignored in current design practice for buildings which are sealed and interface with the outside through a ventilation system.

#### 4.3 Forces and Moments

Mean base moments in the tower referred to street level have been measured by two separate methods: spatial integration of mean pressure measurements, and dynamic balance measurements. A comparison of the two methods is shown in Figure 12. The results are in good agreement. The distribution with height of mean frame pressure, shear and moment for two wind directions has been plotted in Figure 11 from Table 7 which lists mean pressure, shear and moment distributions in the building for

36 wind directions. The loads are shown in Table 7 and Figure 11 for the circular tower, north wing and west wing separately.

Fluctuating base moments were obtained using the dynamic balance. Peak base moments were computed as described in Section 3.5 and Appendix C. The peak base moments, along with the mean and mean  $\pm 1$  rms, are shown in Figure 13. These are response base moments which include both the applied wind load and the inertial response of the structure at its natural frequency. Dynamic measurements were made for 36 wind directions for Configuration A (without Phase II in place) and Configuration B (with Phase II in place). The building dynamic properties used in the various dynamic calculations are shown in Table 4. The peak moments of Figure 13 are appropriate for frame design.

The base moments of Figure 13 show a consistent pattern. Mean x and y moments show a sinusoidal pattern associated with the mean along-wind load. Peak moments show a crosswind excitation for the X moment and a small along-wind excitation for the y moment. These two tendencies cause the maximum loads about both x and y axes to occur for winds just east of north and just west of south.

Torsional moments, shown in Figure 13, show that maximum magnitudes should occur for winds approaching from 60-90 degrees in azimuth. The peak magnitude coincides with the wind direction for peak mean torsion. The torsion moment magnitudes were not large.

#### 4.4 Accelerations

It is generally agreed that acceleration provides the best measure of possible human discomfort due to motion in tall structures; however, there is very little data available by which this issue can be judged quantitatively. Approximately five sources are available in the

literature which address this problem: Chang [12], Chen and Robertson [13], Hansen et al. [14], Irwin [15], and the Canadian Building Code [16].

The paper by Chang is the earliest of these, and does not have the benefit of some later research. His suggestions, which are based on data extrapolated from aircraft industry tests conducted at a much higher frequency range than is directly applicable to tall structure vibration, may be summarized as follows: acceleration levels less than 0.0035 g are not perceptible, and levels from 0.0035 g to 0.011 g are at the threshold of perceptibility. Whether or not the quoted accelerations are peak or rms values and the effects of the frequency and duration of the vibration are not identified. Also, no specific recommendation regarding recurrence intervals or the degree of perception or objection by the occupants is made.

Chang also quotes the results of experiments by Feld [17], who studied human response to vibration for application to the design of the World Trade Center. The design criterion adopted in that case was a limiting acceleration of 0.007 g not to exceed an occurrence rate of 12 times a year. Such a high recurrence rate implies that 0.007 g is being interpreted as the threshold of perception. These test data were probably obtained at vibration frequencies substantially lower than what will be experienced in the International Place tower, and more recent research indicates that a lower threshold may be applicable to the International Place.

Chang also reports some interesting observations on the Chicago John Hancock Tower: that common motion is probably at the threshold of perception, that 75 percent of the occupants have been aware of motion, and "almost all persons had adapted to and come to accept sway."

Chen and Robertson reported on a sophisticated series of tests designed to determine the threshold of perception of motion of persons in a realistic office tower environment. The threshold identified in this study was obtained from persons who were trying to detect motion. Motions less than the levels detectable in this study are certainly acceptable, but higher levels of motion may not be detected in an office environment.

Hansen et al. conducted a research program involving acceleration measurements on two tall buildings during one windstorm each, and subsequent interviews of the occupants of the top one-third of each building. It was then determined what percentage of the occupants would "object to" the observed level of motion if it occurred at various recurrence intervals. The acceleration levels involved were 0.002 g and 0.005 g (rms), and only these two motion intensities could be analyzed. Their results are summarized in Figure 14.

A key feature of Hansen's interpretation is that a person's objection depends not only on the level of acceleration, but also on the recurrence interval of that acceleration. For any given acceleration level, there is a continuous function associating levels of objection with recurrence intervals. Figure 14 shows two such functions Hansen found for acceleration levels of 0.002 g and 0.005 g. Note that under this interpretation a question such as, "How many times a year will X percent of the people object?" has no relevance; the appropriate question is, "How many people will object?"

Their suggested performance criterion is that no more than 2 percent of the (top one-third of the) building occupants should object to the motion. This criterion may be met by various combinations of

acceleration/recurrence interval combinations, one of which is an acceleration of 0.005 g rms every six years. Another possible combination would be 0.002 g rms every (approximately) 1.5 years.

Irwin has reviewed a large amount of data regarding many aspects of human response to vibration, and included frequency of motion as a variable which strongly affects this response. Concerning normal activities in tall buildings, his suggested criterion (and interpretation thereof) is the same as that proposed by Hansen et al., except that allowances are made for a much broader frequency range. For example, his suggested maximum rms acceleration for a 5-year recurrence interval--that which will produce a 2 percent objection level--is 0.005 g at a frequency of 0.2 Hz, and decreases to 0.0033 at 0.6 Hz and 0.0028 g at frequencies 1 Hz and higher. He also presents an application to offshore drilling platforms which suggests that trained personnel can perform routine skilled tasks adequately in such an environment at much higher motion levels. Irwin's suggested design acceleration for the offshore platform case is in fact six times higher than that for ordinary tall buildings. This increased allowance follows the notion that a person's tolerance for motion can be increased if he is trained to expect it. This allowance is perhaps not applied to normal tall buildings since the lay person who inhabits it normally believes that buildings should not move at all.

Finally, the National Building Code of Canada (NBC) suggests that the perception threshold of rms acceleration is from 0.0013 g to 0.0039 g, and that suitable design limits for a 10-year recurrence interval are about 0.0026 to 0.0079 g.\* The lower limit is suggested to

---

\*Actual values stated in the code are higher, and represent peak accelerations. Suitable allowance has been made to convert them to rms values.

apply to residential buildings and the upper limit to office buildings. This seems to be in agreement with the previously discussed notion that trained personnel performing skilled tasks have a higher tolerance level.

This NBC criterion appears to be more permissive than others described above for building application; however, the following should be noted: the NBC provisions used to estimate acceleration in structures assumes that wind comes from the least favorable (most critical) direction, and so the limiting criteria must also be applied at that wind direction.

All of the human-response data found in the literature and discussed above, except that of Chang, is conveniently summarized in Figure 15.

In contrast to the design pressures developed herein, acceleration limits are not a straightforward engineering problem for which a right or wrong solution exists. Criteria suggested in the literature range from a "low" of 0.002 g every 1.5 years, or 0.005 g every 6 years (Hansen et al., and agreed with by Irwin for buildings), to a "high" of 0.011 g every 10 years (NBC Canada). Adoption of any of these proposals is an issue of subjective judgment, and may also be subject to the economics and feasibility of the particular situation. Thus, an ideal structure should meet Hansen's criteria, but if this cannot be met or can be met only with extreme costs, then higher motion levels can be accepted. This latitude exists because the issue is one of performance, and not safety.

Without knowledge of these issues regarding the International Place tower, it is suggested that a subjective decision be made as follows.

Hansen et al. have developed the most rational method of specifying a limit, i.e., the concept of allowing many different acceleration level/recurrence interval combinations. However, their adoption of a 2 percent objection level is arbitrary and quite possibly too low, at least for other than residential buildings. Irwin is in agreement with them for residential buildings, but suggests allowable accelerations six times higher for active working environments (e.g., offshore drilling platforms or bridge maintenance). This is probably too high for the office tower environment. The Canadian Building Code suggests that office buildings can accept three times the acceleration of a residential building. Therefore, a suitable limit might be three times that suggested by Hansen. His data was obtained from buildings with a slightly lower frequency than the International Place tower, and both Irwin and Chen and Robertson indicated that an adjustment in acceleration limit be made to account for the difference in frequency. This can be done based on Irwin's data, which implies an increase factor of nearly 1.0 (assuming a natural frequency of 0.20 Hz). The net result of these two factors (3 for a more liberal motion tolerance, and 1.0 for the increased frequency) is that Hansen's acceleration data can be increased by a factor of 3.0 while maintaining the same recurrence rates and objection levels.

Figure 16 shows how these acceleration criteria compare to the predicted acceleration in the Phase I tower at the top-floor level. This graph shows various levels of total rms acceleration on the top floor plotted against the number of times per year that such a level is expected to occur, for three frequencies and two different damping ratios which may reasonably bound the values expected in the tower. The

accelerations are for combined bending and torsion, although the torsional contribution was small. The dashed lines represent acceleration levels representing the lower limit of perception and objection levels for 2, 10, and 20 percent perception level modified as discussed above. Also shown is the modified perception limit as calculated above. This level can be thought of as a level which will bring the motion to the forethought of someone busy at other tasks.

Figure 16 indicates that, at the highest value of damping, 10 percent of the top floor corner occupants might, if trying to sense motion, be able to perceive motion about 10 to 15 times per year. The modified acceptance level for 2 percent is not significantly exceeded for any damping ratio.

At very low frequencies of occurrence (i.e., high acceleration levels), no data are available by which to judge the human response issue. It is generally agreed, however, that performance-type criteria such as occupant comfort should be based on events which occur relatively frequently, say once per year. The acceleration evaluation was based on criteria which were derived from a very limited amount of research and field data, which nevertheless represent the best criteria available.

**TABLES**

TABLE 1  
CALCULATION OF REFERENCE PRESSURE

1. Basic wind speed from statistical analysis of Boston fastest mile and hourly winds\*:

largest 100-year hourly mean wind at gradient = 101 mph from NE

Reference Pressure at reference velocity location

$$= (0.00256) (101)^2 = \underline{26 \text{ psf.}}$$

2. Wind directionality factors for Boston

Wind Direction	100-yr Gradient Wind Speed	Gradient Height ft	Power Law Exponent	Wind Tunnel Ref. Velocity Height, ft	Direction Load Ratio Based on 26 psf Gradient Level from N.E.
N (0°)	82	1400	0.29	900	0.51
NNE (22°)	91	1400	0.29	900	0.63
NE (45°)	101	900	0.17	900	1.00
ENE (67°)	90	900	0.17	900	0.79
E (90°)	88	900	0.17	900	0.76
ESE (112°)	90	900	0.17	900	0.79
SE (135°)	91	1200	0.23	900	0.71
SSE (157°)	95	1200	0.23	900	0.78
S (180°)	100	1200	0.23	900	0.86
SSW (202°)	94	1200	0.23	900	0.76
SW (225°)	92	1400	0.29	900	0.64
WSW (247°)	89	1400	0.29	900	0.60
W (270°)	85	1400	0.29	900	0.55
WNW (292°)	85	1400	0.29	900	0.55
NW (315°)	88	1400	0.29	900	0.59
NNW (337°)	86	1400	0.29	900	0.56

3. Factor to convert 100-yr loads to 50-yr loads: Divide 100-yr loads by 1.08 to obtain 50-yr loads.

\*Data from National Climatic Center, Asheville, North Carolina.

**APPENDIX B**

**MEASUREMENT AND ANALYSIS  
OF ACCELERATION**

## APPENDIX B

## MEASUREMENT AND ANALYSIS OF ACCELERATION

This appendix deals with the acceleration of a given floor--say the top floor--of a tall building. It is assumed that the motion occurs entirely within the horizontal x-y plane. The motion of an arbitrary two-dimensional body is indicated in Figure B-1. At any given point P(x,y) the acceleration vector  $\underline{a}$  can be resolved into two orthogonal components of magnitude  $a_x$  and  $a_y$ :

$$\underline{a} = a_x \underline{i} + a_y \underline{j} \quad (\text{B.1})$$

Two accelerometers would be both necessary and sufficient to determine the acceleration at this given point. Since the body can rotate about the point 0 (its own z-axis), however, the two accelerometers are insufficient to determine the acceleration at any other point; that is,  $a_x$ ,  $a_y$ , and therefore  $\underline{a}$  are functions of x and y as well as of time.

The entire acceleration field can be specified using three variables  $\ddot{x}$ ,  $\ddot{y}$ , and  $\ddot{\theta}$ , as shown in Figure B-2:

$$\underline{a}(x,y) = \ddot{x} \underline{i} + \ddot{y} \underline{j} + r\ddot{\theta} \underline{t} \quad (\text{B.2})$$

where

$\underline{a}(x,y)$  = total acceleration at a point P(x,y) having

distance  $r = \sqrt{x^2 + y^2}$  from center of twist 0

$\ddot{x}$  = acceleration due to translation of body along x-axis

$\ddot{y}$  = acceleration due to translation of body along y-axis

$\ddot{\theta}$  = angular acceleration (in radians/sec<sup>2</sup>) due rotation  
of body about z-axis (assumed center of twist)

$\underline{t}$  = unit tangent vector =  $-(y/r) \underline{i} + (x/r) \underline{j}$

Figure B-1. Total Acceleration Vector at Various Points on a Two-Dimensional Body

Figure B-2. Total Acceleration Vector as the Sum of Three Components in the X-Y Plane

This equation can be easily expanded to the form of Equation (B.1), which clearly indicates that  $a_x$  is due to both  $\ddot{x}$ ,  $\ddot{\theta}$ , and  $a_y$  is due to both  $\ddot{y}$ ,  $\ddot{\theta}$ :

$$\begin{aligned}\underline{a}(x,y) &= \ddot{x} \underline{i} + \ddot{y} \underline{j} - (y/r)(r\ddot{\theta})\underline{i} + (x/r)(r\ddot{\theta})\underline{j} \\ &= (\ddot{x}-y\ddot{\theta})\underline{i} + (\ddot{y}+x\ddot{\theta})\underline{j} \\ &= a_x \underline{i} + a_y \underline{j}\end{aligned}$$

Now the magnitude of the acceleration is given by

$$\begin{aligned}a^2 &= a_x^2 + a_y^2 = \ddot{x}^2 - 2y \ddot{x} \ddot{\theta} + y^2 \ddot{\theta}^2 + \ddot{y}^2 + 2x \ddot{y} \ddot{\theta} + x^2 \ddot{\theta}^2 \\ &= \ddot{x}^2 + \ddot{y}^2 + (x^2+y^2) \ddot{\theta}^2 - 2\ddot{\theta}(\ddot{x}y-x\ddot{y})\end{aligned}$$

Statistics of the acceleration are determined by time-averaging this equation over a period  $T$  as follows:

$$\begin{aligned}\overline{a^2} &= \frac{1}{T} \int_0^T a^2 dt = \frac{1}{T} \int_0^T (\ddot{x}^2 + \ddot{y}^2 + r^2 \ddot{\theta}^2 - \ddot{\theta}(\ddot{x}y-x\ddot{y})) dt \\ &= \overline{\ddot{x}^2} + \overline{\ddot{y}^2} + \overline{r^2 \ddot{\theta}^2} + \overline{x \ddot{y} \ddot{\theta}} - \overline{y \ddot{x} \ddot{\theta}}\end{aligned}$$

If the rotational motion is assumed to be independent of the translational motions, then the cross-correlations vanish, resulting in

$$\sigma_a = \sqrt{\overline{a^2}} = \sqrt{\sigma_{\ddot{x}}^2 + \sigma_{\ddot{y}}^2 + \sigma_{r\ddot{\theta}}^2} \quad (\text{B.3})$$

### Reduction to SDOF System Using Modal Analysis

A common analytical model of a tall building, suitable for the analysis of dynamic horizontal loading, is to consider it a chain of lumped masses, connected in series by beam elements. Displacements in the x-direction, y-direction, and rotations about the (vertical) z-axis are considered independently. For each of these components, the structural "frame" model will have  $n$  degrees of freedom, corresponding to the side-sway (or rotation) of each floor or lumped mass point. The system may then be described by an  $n \times n$  stiffness matrix  $[k]$ , with an "input"  $n$ -component load vector  $\{P\}$ , and an "output"  $n$ -component displacement vector  $\{x\}$ .

In a static system, these are related by the familiar equation

$$\{P\} = [k]\{x\}$$

When the loading varies with time and height, however, a complete description would be

$$[m]\{\ddot{x}\} + [c]\{\dot{x}\} + [k]\{x\} = \{P\}$$

where  $[m]$  is the matrix of lumped masses,  $[c]$  is a matrix of damping coefficients, and  $\{x\}$  and  $\{P\}$  are now functions of time. This represents a system of  $n$  simultaneous equations, which would be difficult to solve even if  $\{P\}$  could be determined. If a transformation to a system of "generalized coordinates" is applied, these simultaneous equations are simplified to  $n$  uncoupled equations. Each equation corresponds to one of the generalized coordinates,  $\xi_i$ , which also has an associated natural frequency  $f_i$  and mode shape  $\{\phi\}_i$ . Furthermore, due to the frequency distribution of wind energy, almost all of the excitation occurs in the fundamental mode associated with the lowest

natural frequency. It is then only necessary to consider the first of the generalized coordinate equations, which appears as

$$m^* \ddot{\xi} + c^* \dot{\xi} + k^* \xi = P^* \quad (C.1)$$

where

$$m^* = \{\phi\}^T [m] \{\phi\}$$

$$c^* = \{\phi\}^T [c] \{\phi\}$$

$$k^* = \{\phi\}^T [k] \{\phi\}$$

$$P^* = \{\phi\}^T \{P\}$$

These are referred to as the generalized mass, damping, stiffness, and load, respectively. This governing equation is that of a conventional single-degree of freedom system. The solution of the system,  $\xi$ , is related to the actual system by

$$\{x\} = \xi \{\phi\} . \quad (C.2)$$

It can be shown that the natural frequency of the system is

$$f_0 = \frac{1}{2\pi} \sqrt{k^*/m^*} . \quad (C.3)$$

A further key property of tall structures is that the mode shape may be approximated by a straight line, that is  $\phi_i = \alpha z_i$  or  $\{\phi\} = \alpha \{z\}$ . Since the magnitude of a mode shape is arbitrary,  $\alpha$  may be taken as unity. The generalized mass then becomes

$$m^* = \{z\}^T [m] \{z\} = \sum_i m_i z_i^2 \quad (C.4)$$

which is approximately the mass moment of inertia,  $I$ , about the base.

The generalized load is

$$P^* = \{z\}^T \{P\} = \sum_i P_i z_i \quad (C.5)$$

which is the moment about the base,  $M$ . The displacement vector is

$$\{x\} = \xi\{z\}, \text{ or } x(z) = \xi z$$

which shows that  $\xi$  is the rotation of the structure (which remains a straight line by assumption) about its base,  $\theta$ . By analogy to the SDOF system the generalized stiffness  $k^*$  is equivalent to a simple rotational stiffness  $k_\theta$ . Introducing the critical damping ratio,

$$\begin{aligned} \zeta &= \frac{c}{c_{cr}} = \frac{c^*}{c_{cr}^*} = \frac{c^*}{2\sqrt{k^*m^*}} \\ &= 2m^*\omega_0 \end{aligned}$$

where  $\omega_0 = 2\pi f_0$  is the natural circular frequency, the governing equation (C.1) may be rewritten as

$$I\ddot{\theta} + 2I\zeta\omega_0\dot{\theta} + k_\theta\theta = M(t) \quad (C.6)$$

#### Solution of the Governing Equation Using Random Vibration Theory

Equation (C.6) is most easily solved in the frequency domain when the loading  $M(t)$  is random in time, since an arbitrary function of time can be described by a superposition of sinusoidal functions. For such a harmonic function at frequency  $f$ ,

$$M(t) = M_0 \sin(2\pi ft + \psi),$$

the solution is (in magnitude, ignoring phase)

$$\theta(t) = \frac{1}{k_\theta} |H(f)| \cdot M(t)$$

where the frequency response function  $H(f)$  is defined as

$$|H(f)| = \frac{1}{\sqrt{[1-(f/f_0)^2]^2 + (2\zeta f/f_0)^2}}$$

In terms of the spring load , which is equal to

$$= k_\theta\theta,$$

the solution is simply

$$M(t) = |H(f)| \cdot M(t) .$$

Note that  $M(t)$  and  $M(t)$  are both moments, and that  $|H(f)|$  is dimensionless. If the driving frequency  $f$  is near the structure's natural frequency  $f_0$ , and the damping ratio  $\zeta$  is low, this function is an amplification factor describing a condition known as resonance.  $M(t)$  is properly described as an externally applied base moment, whereas  $M(t)$  is an internal or "response" base moment. Note that if  $M(t)$  were externally applied to the structure and a static analysis performed, the calculated response (displacement or internal forces) would be the same as the actual response due to the real fluctuating load  $M(t)$ . Thus  $M(t)$  is also referred to as a "static equivalent load."

When the loading  $M(t)$  is random in time, its statistical description as a superposition of harmonics is its "power spectral density," denoted  $S_M(f)$ . The response moment is then also described as a power spectral density,  $S_M(f)$ . The general result of random vibration theory is the relationship between these two, which is simply

$$S_M(f) = |H(f)|^2 \cdot S_M(f) \quad (C.7)$$

The relating function  $|H(f)|^2$  is just the square of the frequency response function, and is referred to in general as the transfer function:

$$|H(f)|^2 = \frac{1}{[1-(f/f_0)^2]^2 + (2\zeta f/f_0)^2} \quad (C.8)$$

This particular transfer function is also referred to as the "mechanical admittance."

The principal usefulness of the power spectral density of a function is that its variance may be computed as the area under the spectrum:

$$\sigma_M^2 = \int_0^{\infty} S_M(f) df \quad (C.9)$$

The response is expected to be normally distributed (Gaussian) statistically, and thus can be completely described by its variance  $\sigma_M^2$  and mean value  $\bar{M}$  (note that the mean response  $\bar{M}$  is equal to the mean load  $\bar{M}$ ). Since the structural damping is very low, the response is also "narrow band," i.e., it can be loosely described as vibration at a single frequency  $f_0$  with randomly varying amplitude. Each cycle of vibration has a maximum and negative "peak" value associated with it. It is this series of peaks which are of interest insofar as structural design for strength or stiffness is concerned. It can be shown that these peak values obey a Rayleigh probability distribution, which is easily obtained from  $\sigma_M^2$ . The expected value, variance, etc. of these peaks could be easily found from the Rayleigh distribution. What is more desirable, however, are statistics describing the largest peak which is likely to occur. Such an analysis is beyond the scope of this review, and the following result is simply stated:

$$\hat{M} = \bar{M} + g_p \sigma_M \quad (C.10)$$

Here  $\hat{M}$  is the expected value of the largest peak  $M$  occurring during a duration  $T$  of the loading  $M$ . The so-called "peak factor"  $g_p$  is calculated as follows [C3]

$$g_p = \mu + \frac{.5772\mu}{\mu^2 - 1} \quad (C.11)$$

where 
$$\mu = \sqrt{2 \ln v T} + \frac{\ln \sqrt{2 \ln v T}}{\sqrt{2 \ln v T}}$$

$$v = f_0 \sqrt{8 \zeta}$$

Nomenclature

$[c]$	Damping matrix
$c^*$	Generalized damping
$f_0$	Natural cyclic frequency of fundamental mode
$g$	Peak factor
$ H(f) ^2$	Mechanical admittance (transfer function)
$I$	Mass moment of inertia of fundamental mode approximated by straight-line shape
$[k]$	Stiffness matrix
$k^*$	Generalized stiffness
$k_\theta$	Rotational stiffness of fundamental mode approximated by straight-line shape
$M$	Resultant base moment of externally-applied wind load
$M$	Response (internal, static equivalent) base moment
$[m]$	Mass matrix
$m^*$	Generalized mass
$m_i$	Mass lumped at floor $i$
$\{P\}$	Vector of $P_i$
$P_i$	Resultant force of wind load acting at floor $i$
$P^*$	Generalized load
$S_{( )}(f)$	Power spectral density of ( )
$\{x\}$	Vector of floor displacements
$\{z\}$	Vector of $z_i$
$z_i$	Height of floor $i$
$\zeta$	Critical damping ratio
$\theta$	Rotation of fundamental mode approximated by straight-line shape
$\xi$	Generalized coordinate
$\sigma_{( )}$	Standard deviation (fluctuating rms) of ( )

$\sigma^2$ ( )	Variance of ( )
{ $\phi$ }	Mode shape
$\psi$	Phase angle
$\omega_o$	Natural circular frequency
( $\bar{\quad}$ )	Temporal mean of ( )
( $\hat{\quad}$ )	Expected peak value of ( )
