## ACKNOWLEDGMENTS

For many years now we have taken this opportunity to thank the many cooperative weather observers in Colorado and thrir National Weather Service supervisors, William Tate and Michael Elias, for making it possible to monitor the climate in all parts of Colorado at a very low cost. Again, our sincere thanks are in order.

The authors also wish to express their appreciation to Odilia Bliss for doing a fine job of preparing and processing each month's climate data and assembling this finished product. The work of John Kleist in automating much of the data analysis and in improving the appearance of each monthly report has been very helpful.

These summaries have been made possible by funding for the Colorado Climate Center through the CSU Agricultural Experiment Station.

## I. INTRODUCTION

The 1985 Water Year marked the 12th year of existence of the Colorado Climate Center (CCC) and the 9th year of closely monitoring the climate of this diverse and interesting state. The first monthly cl imate summary prepared by the CCC was written in early 1977 in the midst of an unprecedented severe winter drought. Since that time Colorado has experienced a myriad of extremes -- record winter cold, incredible snowstorms, disastrous hail storms and several of the snowiest years in the past half century. Our monthly descriptions of Colorado climate have expanded to document and describe as much of this information as possible.

The monthly climate descriptions are intended to accomplish several purposes. They are a written historical record of what our climate has been which can hopefully always be used as a reference in the future. By tracking monthly departures of temperature and precipitation from long-term normals, these summaries have also become tools for operations, planning and policy-making related to agriculture, water resources, land use and energy. Finally these summaries are used to educate the people of Colorado about our unique climate and its impact on our lives and livel ihoods.

In Colorado, the Water Year (October 1 through September 30) is the most appropriate period for monitoring climate. This 12 -month period is directly correlated with the state's water storage--water usage cycle. In October snow usually begins to accumulate in the high mountains. As
winter progresses, the snowpack normally continues to build up. This snow is the frozen reservoir which supports the huge ski and winter recreation industry. Eventually it supplies much of the water for human consumption, for extensive irrigation, for industry, and to satisfy long-standing stream flow compacts with neighboring states. Irrigated agriculture still accounts for the vast majority of water used in Colorado. Therefore, demand for water peaks during the summer and tapers off as temperatures drop, crops are harvested, and autumn arrives. September marks an appropriate end to the water year.

Because of the crucial importance of water to Colorado, this publication emphasizes precipitation and water-year accumulated precipitation. Comparisons with long-term averages are made to help determine which parts of the state are wetter or drier than average. This makes it possible to document the availability of water resources and to assess potential drought situations.

A new format was developed during the 1985 Water Year for displaying and describing the month by month climate. The following paragraphs describe the information content of this new report format.

Each month's summary begins with a brief one-paraoraph description of observed general temperature and precipitation patterns. This is followed by a new feature, "A Look Ahead." This section is not a forecast in the normal sense but is a generalized statewide climatological description (based on past records) of what weather conditions can most typically be expected. This section is really designed as an educational tool for newcomers to Colorado and to those just learning about climate to help familiarize themselves with the nature of our climate. It is also a potential planning tool for those
individuals, businesses, researchers, and government agencies who are just starting to try to take climate into account in planning and scheduling activities.

In December 1984 a new feature was added to the monthly summary. Each month a topic of special interest to climate information users in Colorado was presented. During the 1985 Water Year special topics included:

1) The oldest weather station in Colorado (Dec 1984).
2) A new average precipitation map for Colorado (Jan 1985).
3) A new all-time record cold temperature for Colorado (Feb 1985).
4) Where do climate data come from (Mar 1985).
5) Berthoud Pass weather station closes (Apr 1985).
6) Steamboat Springs long-time weather observer dies (May 1985).
7) Heaviest rainfall in Colorado (Jun 1985).
8) Autumn frost (Jul 1985).
9) How often does precipitation fall (Aug 1985).
10) 1985 Water Year wrap-up (Sep 1985).

The feature will be continued in the future.
The daily weather description, which has been a part of the monthly summary for several years, has been continued and now includes a table of extremes of temperature, precipitation and snow. This narrative section gives the dates of major storms, heat waves and cold blasts and gives selected examples from across Colorado.

One page is dedicated each month to the precipitation pattern. A brief narrative description is followed by a list of the wettest and driest National Weather Service reporting stations. A detailed map showing precipitation amounts is contoured to show which areas were above and below average.

The next page of the summary includes a similar assessment of the water year accumulated precipitation. A brief narrative comparison is made between the current and the past year's precipitation. This accompanies the narrative description, tabular data and a contoured map analysis of the current year's accumulated precipitation.

Temperature data for the month and comparisons to average are described in a short paragraph. The monthly temperatures for approximately 55 selected locations are plotted on a map and are analyzed using contour lines of departures from the 1961-80 averages. Another new feature has been added this year and placed on the "temperature" page. A detailed analysis of Fort Collins daily soil temperatures at several depths is presented. Soil temperature is an important climatic element in agriculture, construction, and energy conservation. Unfortunately, detailed soil temperature data are not available throughout Colorado.

Heating degree day data for 36 Colorado cities is published each month in a data table similar to previous years. A description of heating degree days and their use is given in Section II of this report.

The new summary format ends with two pages of tabular climate information for the month for selected Colorado stations. Stations are divided into 4 regions: the Eastern Plains, the Foothills/Adjacent Plains (includes the Front Range urban corridor), the Mountains and High Interior Valleys, and the Western Valleys (includes stations in western Colorado below 7,000 feet). Data presented for each station include the average high, low and mean temperature for the month and the departure from the 1961-1980 average, the highest and lowest temperature recorded during the month, the monthly total of heating, cool ing and arowing
degree days (see Section II for definitions), the monthly total precipitation, the departure from the 1961-1980 average, the percent of the 1961-1980 average, and the total number of days with measurable precipitation.

The final information contained in each monthly report is a comparative table of number of clear, partly cloudy and cloudy days and the percent of possible sunshine for 5 National Weather Service stations. This is followed by a graph of daily total solar radiation data measured at Fort Collins.

Specific daily temperature and precipitation data are not listed here. Daily data can be obtained in digital and/or hard copy form from the Colorado Climate Center and the National Climatic Data Center (Asheville, NC). Much of the daily data are published in the government document, Climatological Data.

Most temperature and precipitation data used in the monthly summaries were obtained from the National Weather Service cooperative observer network. Data from the major National Weather Service stations, such as Denver and Grand Junction, are also used extensively.

The averages which are used in this report for both temperature and precipitation were calculated using 1961-1980 data. Heating degree day normals were based on 1951-1980 data.

The written descriptions give a good general accounting of each month's weather, but the maiority of information is contained on the maps and tables which accompany each report. The accuracy of all of these maps and tables is usually quite good. However, these reports were initially prepared soon after the end of each month, and prel iminary information had to be used. Therefore, some of the
precipitation, temperature, and heating, cool ing and growing degree day values may differ slightly from what is later published by the National C1imatic Data Center.
II. EXPLANATION OF DEGREE DAYS

Many climatic factors affect fuel consumption for heating and cooling. Wind, solar radiation and humidity all play a part, but temperature is by far the most important element. Very simply, the colder it gets; the more energy is needed to stay warm.

A simple index, given the name, heating degree days, was devised several years ago to relate air temperatures to energy consumption (for heating). The number of heating degrees for a given day is calculated by subtracting the mean daily temperature (the average of the daily high and low temperature) from $65^{\circ} \mathrm{F}$. Sixty-five degrees is used as the base temperature because at that temperature a typical building will not require any heating to maintain comfortable indoor temperatures. That difference $\left(65^{\circ} \mathrm{F}\right.$ minus the mean daily temperature) is the number of heating degrees for that day. The daily values are accumulated throughout the heating season to give heating degree day totals. Different base temperatures can be used to calculate heating degree days, but $65^{\circ}$ is the long-standing traditional base.

The heating degree day total for a month or for an entire heating season is approximately proportional to the quantity of fuel consumed for heating. Therefore, the colder it gets and the longer it stays cold, the more heating degree days are accumulated and the more energy is required to heat buildings to a comfortable temperature.

So why is this important? Very simply, if you know how much energy you have used for heating your home or business during a certain period
of time, and if you also know the heating degree day total for the same period, you can then establish an energy consumption ratio. With that information you can then make reasonable estimates of your future energy consumption and costs. Also, you can easily check the success and calculate the savings resulting from energy conservation measures such as new insulation, storm windows or lowering the thermostat.

Cooling degree days are calculated in a similar fashion. Cooling degrees occur each day the daily mean temperature is above $65^{\circ} \mathrm{F}$. They are accumulated each day throughout the cooling season and are roughly proportional to the amount of energy required to cool a building to a comfortable inside temperature. Cooling degree days are less useful than heating degree days, especially here in Colorado where air conditioning requirements are minimal in many parts of the state. However, they still offer a means of making general comparisons from site to site, year to year or month to month.

Growing degree days are a measure of temperature which has been found to correlate with the rate of development and maturation of crops. Several methods exist for computing growing degree days. In this report the "corn" growing degree day definition was used. The optimum growth occurs at $86^{\circ} \mathrm{F}$ and essentially no growth occurs at temperatures below $50^{\circ} \mathrm{F}$. Therefore, when computing the daily mean temperature any minimum temperature below $50^{\circ}$ is counted at $50^{\circ}$ and any maximum above $86^{\circ}$ is counted as $86^{\circ}$. Growing degree day totals are this adjusted mean temperature ( ${ }^{\circ} \mathrm{F}$ ) minus $50^{\circ} \mathrm{F}$ summed for each day.
III. 1985 WATER-YEAR IN REVIEW

In previous years several pages have been written recapping the highlights of the year's climate and the impact it had on Colorado. Because of the expanded format of each monthly report, and the fact that most information in this section was simply repeated from the original monthly reports, we will no longer be publishing this segment. The impacts were also extremely difficult to assess and document easily and accurately. We regret the omission of this section.

# COLORADO CLIMATE -- OCTOBER 1984 

Colorado Climate Center<br>Department of Atmospheric Science Fort Collins, Colorado 80523

The 1985 water year got off to a very cold and wet start. All of Colorado was several degrees cooler than average in October. Precipitation was abundant statewide with several reports of more than $500 \%$ of average in the vicinity of Colorado Springs. Record monthly snowfall was also reported at a few locations. It was the "lousiest" October since 1969.

## Significant Highlights -- October

Date
1-5 A slow moving "cut off" low pressure area drifted toward Colorado. Rainshowers began on the Western Slope early on the 1st. Palisade totalled 1.10" on the 1st. By late in the day on the 2nd, precipitation began to spread into eastern Colorado. As the low moved across southern Colorado, steady upslope rains developed which lasted for more than 48 hours in some areas. All of the state received precipitation, but the heaviest rains fell along the Front Range. Storm totals of 2" were common, but Lakewood's 3.64" total (2.93" in 24 hours) and 3.92" at Ruxton Park on the north side of Pikes Peak were the greatest in the state. Temperatures throughout this period were mild. Holly and Walsh each recorded $85^{\circ}$ on the 2nd, the state's warmest temperatures for this October.

11 The warmest weather of the month over much of the state preceeded a Pacific cold front. Craig reached $70^{\circ} \mathrm{F}$. Upper 70s were common east of the mountains. Pueblo and Sterling each reached $80^{\circ}$.

12-14 $\quad \begin{aligned} & \text { A Pacific cold front crossed the state on the } 12 \text { th bringing } \\ & \text { cooler temperatures and moderate rain and snow showers west }\end{aligned}$
A Pacific cold front crossed the state on the 12th bringing
cooler temperatures and moderate rain and snow showers west
Fine fall weather with daytime temperatures mostly in the 50 s in the mountains and $60 \mathrm{~s}-70 \mathrm{~s}$ at lower elevations. Just a few scattered light showers from the mountains eastward on the 8th and 9th still caused by the same storm system from the previous week. The only significant rains occurred in southeast Colorado where more than $0.50^{\prime \prime}$ fell on the night of the 8 th in some locations. Holly totalled $1.16^{\prime \prime}$ of rain.
of the Continental Divide. Meeker received 0.56 " of rain on the 12th. Berthoud Pass and Climax both picked up $6^{\prime \prime}$ of snow. By the 14 th, a stronger cold front made its way across the state. A major winter-type storm system began to take shape over the Rockies, and rain and snow began falling.

15-16 Major winter storm brought much colder temperatures and widespread snowfall. Precipitation fell statewide but was heaviest in the southwest and across the eastern half of the state. Wolf Creek Pass received nearly 3 feet of new snow in just 24 hours. Snowfall in amounts of $6-18{ }^{\prime \prime}$ were common in the San Juans, even at lower elevations. But the heaviest snows fell east of the Continental Divide. Blizzard conditions developed on the 16th on the Palmer Lake Divide south and southeast of Denver. Both the Mount Evans and Pikes Peak areas received nearly 4 feet of snow in only about 24 hours. Heavy snow also fell on the plains. Denver and Boulder each received about a foot of snow, but nearby reports ranged from $15^{\prime \prime}$ at Limon and 18.5" at Colorado Springs to 20" at Lakewood, 27" at Palmer Lake and 35" northeast of Colorado Springs near Eastonville. Even as far east as Burlington, 10 " of snow fell. The snow had substantial water content as well -- more than $2^{\prime \prime}$ in many places. A report of 3.50 " of precipitation came from the Conifer area.

17-25 Unseasonably cold with most days $10-20$ degrees below average. The first subzero temperatures of the year occurred on the 20th when Ruxton Park and Rio Grande Reservoir dipped to $-1^{\circ}$ and $-2^{\circ} \mathrm{F}$, respectively. Unsettled with daily mountain snows and several periods of snow and rain at lower elevations. The southeastern plains received some heavy rains on the 24 th such as the $1.55^{\prime \prime}$ reported at Holly. The coldest temperature of the month occurred at Antero Reservoir on the morning of the $25 \mathrm{th},-3^{\circ} \mathrm{F}$.

26-31 A strong upper air disturbance brought 4-12" of new snow to the Northern and Central Mountains on the 26-28th. Otherwise it was dry over the rest of the state and temperatures returned to more seasonal allowing the remaining snow to melt. An arctic cold front "backed" into northeastern Colorado on the 30th leaving daytime temperatures only in the 30s. But it quickly retreated on the 31st leaving sunshine and temperatures mostly in the 60s (40s and 50 s in the mountains).

## Precipitation Summary

Precipitation totals for October (the first month of the 1985 water year) and percents of average are shown in Figures 1 and 2. Except for extreme northwest Colorado, the entire state was wetter than average.

Most areas had more than double the average precipitation. From the Front Range eastward across the plains, totals were generally more than $300 \%$ of average. From Denver to Pueblo and along the Kansas border, most stations reported more than 4 times the average October precipitation. New records were set at Colorado Springs (5.01"), Fountain (5.39"), Lakewood (5.75") and Ruxton Park (7.46"). At least a dozen stations totalled more than 5.00 of precipitation for the month. Ruxton Park, northwest of Colorado Springs, was the wettest reporting station. Browns Park Refuge in extreme northwest Colorado was the driest with 0.84".

## Temperature Summary

This was the coldest October since 1969 and one of the coldest on record. Temperatures ranged from about three degrees below average in the northeast and in the San Luis Valley to eight degrees below average in central Colorado. Nighttime temperatures were actually near normal to as much as 3 degrees above normal because of frequent cloud cover. However, daytime temperatures were anywhere from 7 to as much as 14 degrees below average making October feel more like March.

## Degree Days

No cooling degree days occurred in October so the statistics shown at the end of September complete the summer cooling season. Heating degree days are shown in Table 1. Because of the cold weather, heating degree day totals were much higher than usual. As a result energy requirements for heating homes, schools and business in October were as much as $60 \%$ more than average and $70 \%$ more than last year in some areas.

Figure 1. October 1984 precipitation amounts (inches).

Figure 2. Precipitation for October 1984 as a percent of the 1961-80 average.

Figure 3. Temperatures for October 1984 in degrees Fahrenheit (in parentheses) and departures form the 1961-1980 average.

Table 1. Colorado Heating Degree Day Data through October 1984.

Colorado Climate Center Department of Atmospheric Science Colorado State University
Fort Collins, Colorado 80523

## NOVEMBER 1984

## November in Review:

Placid autumn weather was observed in Colorado in November. It was a sharp but pleasant contrast with the cold and stormy early winter weather of October. Temperatures were close to average over the western half of the state, and warmer than average in the east. Precipitation was generally $50 \%$ to $100 \%$ of average west of the Continental Divide. A few small areas in the Northern and Central Mountains were wetter than average. East of the Divide precipitation was very sparse. Twenty stations reported no measurable precipitation for the month.

## A Look Ahead -- January 1985:

January is typically the coldest month of the winter for Colorado. Normal daytime temperatures rise into the 30 s and 40 s from the Eastern Plains into the foothills. The mountains typically see daytime temperatures in the 20s, while readings in the 30 s are normal in the Western Valleys. Local topography has a big effect on nighttime temperatures. Lows are typically near zero high in the mountains but often fall well below zero in the mountain valleys. Nighttime lows average between 10 and $15^{\circ} \mathrm{F}$ over most areas east of the mountains. Boulder and Canon City are noted exceptions as their temperatures often stay in the 20s. One or more episodes of extreme cold can normally be expected in January dropping temperatures below zero over most of the state. There are also usually a few warm "chinook" periods where westerly winds produce "downslope" warming east of the mountains. Occurrences of temperatures in the 50 s and 60 s are not uncommon during these episodes. Some of the worst downslope windstorms have occurred in January along the Front Range causing considerable damage.

January is a very dry month in the San Luis Valley, South Park and over most of eastern Colorado. Major snowstorms are uncommon in these areas and there is usually plenty of sunshine. However in the higher mountains and in areas west of the Continental Divide, January is a cloudy and snowy month. Monthly snowfall totals often exceed 50 inches in the mountains.

## Happy Holidays!

The staff at the Colorado Climate Center wish you and yours a wonderful holiday season and a great new year. We appreciate your interest in the climate of our state and look forward to serving you in the years ahead.

As you can see, we have a new layout for our monthly summary. We hope this is to your liking. Please feel free to contact us with your comments.

Merry Christmas!

## NOVEMBER 1984 DAILY WEATHER

| Date | Event |
| :---: | :---: |
| 1 | Plenty of sunshine but chilly east of the mountains. |
| 2 | Rapid warmup. The warmest day of the month for much of the state with temperatures in the 70 s over most of the Eastern Plains. |
| 3 | A few widely scattered rain and snow showers in and near the mountains associated with an upper air disturbance. |
| 4-7 | Dry and mild. |
| 8-9 | A storm system moved quickly from the West Coast across Colorado producing significant mountain snows particularly in the Northern and Central Mountains. Snows of 6-12" were common. Only a few sprinkles spilled across into eastern Colorado, but some lightning and thunder was observed on the 8th. |
| 10-13 | High pressure ridge over the Rockies brought warm and dry weather. Very warm on the 13th in advance of Pacific storm system. Unusually warm temperatures included $66^{\circ}$ at Montrose, $73^{\circ}$ at Burlington and $78^{\circ}$ at Las Animas. |
| 13-14 | Snow developed late on the 13th in the Northern and Central Mountains. Precipitation was generally light, but the Berthoud Pass-Winter Park area received more than a foot of new snow. |
| 15-21 | Mild days but chilly nights. A storm system over New Mexico spilled into southwestern Colorado 17-18th leaving a few inches of new snow. |
| 22-24 | Warm statewide $-\mathbf{H}^{40}$ s and 50s. Moisture began moving northward into Colorado on the 24th with precipitation developing in the San Juan and Sangre de Cristo Mountains. |
| 25-26 | A moderate winter storm formed over Colorado and moved quickly into the Dakotas. Snow fell over most of western Colorado. Meeker, for example, totalled $6^{\prime \prime}$. For the first time all month, snow developed over portions of eastern Colorado. While the storm only affected a few areas, some heavy amounts were reported such as: Bennett $6^{\prime \prime}$, Trinidad 8", Palmer Lake $1^{\prime \prime}$ and Aguilar 13". |
| 27 | Clear and cold. Temperatures dropped to the teens and single digits over the plains and western valleys with below zero readings in the mountains. Leadville, for example, dipped to $-8^{\circ}$. Crested Butte had a $-21^{\circ}$, while Taylor Park Reservoir took it on the chin with a $-30^{\circ}$ reading. |
| 28-30 | Cold, moist northwesterly flow aloft brought periods of light snow to the mountains and some of the western valleys. Strong winds and warm tempertures along the Front Range on the 28th. Cold but dry in the east 29-30. |

November 1984 Extremes

| Highest Temperature | $80^{\circ} \mathrm{F}$ | November 2 | La Junta 20S |
| :--- | :---: | :--- | :--- |
| Lowest Temperature | $-30^{\circ} \mathrm{F}$ | November 27 | Taylor Park Resvr. |
| Greatest Total Precipitation | $3.92^{\prime \prime}$ |  | Berthoud Pass |
| Least Total Precipitation | 0 |  | Several locations |
| Greatest Snowfall | $54^{\prime \prime}$ |  | Berthoud Pass |
| Greatest Depth of Snow | $37^{\prime \prime}$ | November 5 | Berthoud Pass and |
|  |  | November 29 | Bonham Reservoir |

## NOVEMBER 1984 PRECIPITATION

November precipitation was below average over most of Colorado. Many areas in eastern Colorado received no measurable precipitation. The only areas which were wetter than average included a narrow band along the Continental Divide from Winter Park to Taylor Park, an area in the northern mountains near Steamboat Springs, a very small area on the southwest slopes of the San Juan Mountains and an area from the Sangre de Cristo Range to Trinidad. Only one precipitation event affected eastern Colorado during the entire month.

## Greatest

| 3.92" | Berthoud Pass |
| :--- | :--- |
| $2.80^{\prime \prime}$ | Bonham Reservoir |
| $2.78^{\prime \prime}$ | Wolf Creek Pass |
| $2.39^{\prime \prime}$ | Trout Lake |
| $2.16^{\prime \prime}$ | Pyramid |

## Least

### 0.00" Briggsdale, Eads, Haswell, Kit Carson, Kauffman 4SSE, Waterdale (Loveland)

Precipitation for November 1984 as a percent of the 1961-1980 average.

Despite a dry November, precipitation for the first two months of the 1985 water year is well above average over most of the state. Much of eastern Colorado is still more than 200\% of average for this time of year.

## Comparison to Last Year

Last year at this time, accumulated precipitation was also above average over most of the state. The only dramatic differences were that the southeastern plains and the San Luis Valley were considerably drier last year and the northwestern counties were wetter than they are so far this year.

1985 Water Year to Date through November

| Wettest (as \% of average) |  |  |
| :--- | :--- | :--- |
| Fountain | $527 \%$ | $5.43{ }^{\prime \prime}$ |
| Fort Carson | $497 \%$ | $5.96^{\prime \prime}$ |
| Colorado Springs | $402 \%$ | $5.15^{\prime \prime}$ |
| Inter Canyon | $390 \%$ | $7.41^{\prime \prime}$ |
| Holly | $382 \%$ | 5.23 |

Driest (as \% of average)

| Brown's Park Refuge | $66 \%$ | $1.10^{\prime \prime}$ |
| :--- | :--- | :--- |
| Williams Fork Dam | $85 \%$ | 1.89 " |
| Cimarron | $90 \%$ | $2.15^{\prime \prime}$ |
| Dinosaur Nat Mon | $93 \%$ | $1.88^{\prime \prime}$ |
| Red Feather Lakes | $90 \%$ | $2.15^{\prime \prime}$ |

Precipitation for October through November 1984 as a percent of the 1961-1980 average.

AND DEGREE DAYS

Mean temperature for the month were very near the 1961-80 average. The only areas with significant departures from average were in northeastern Colorado where Fort Collins, Sterling and Akron were all nearly 3 degrees Fahrenheit above average, and also in southeastern Colorado where Holly was more than 4 degrees warmer than a verage.

Because of the seasonal to somewhat warmer than average temperatures experienced this November, heating degree day totals are near to somewhat less than average. Compared to last year, heating degree day totals this year were generally a little lower over most of the state indicating less demand for energy this year for heating purposes. More detailed data appear in the table on the following page.

NOVEMBER 1984 SOIL TEMPERATURES

Soil temperatures are important to a wide number of persons ranging from farmers to excavators. At the present time, systematic measurements of soil temperature are taken at only a few locations in Colorado. Data have been collected in Fort Collins at Colorado State University for several decades. Beginning this month, we will display a monthly graph of Fort Collins soil temperatures. The measurements are taken beneath unirrigated sod with an open exposure.

Table 1. Colorado Heating Degree Day Data through November 1984.

## December in Review:

Temperatures were relatively mild, for December, and precipitation ranged from below average in the Northern and Central Mountains and along the Front Range to much wetter than average over portions of southwestern and west central Colorado. Only two significant storm episodes affected the state. It was a quiet month compared to December 1983 when record cold chilled the Eastern Plains and record breaking snows buried the mountains.

## A Look Ahead -- February 1985:

Daylength becomes noticeably longer in February and a few warm days east of the mountains give early hints of the coming of spring. For the most part, though, February means more winter weather for Colorado. Temperatures begin a gradual warm up over the state. On the average, February temperatures are 1 to 4 degrees Fahrenheit warmer than January in the mountains and foothills. But out on the plains and in some of the western valleys the warmup is more noticeable. At Grand Junction, for example, February temperatures average 10 degrees higher than January. After the first week of February' the chances of seeing below zero temperatures on the Eastern Plains drop dramatically. But in the mountains, subzero temperatures are just as likely in February as in January. Some of Colorado's coldest temperatures have occurred in February such as Taylor Park's well known $-60^{\circ} \mathrm{F}$ reading on February 1, 1951.

February is still a month known for plenty of mountain snows, and the snow that falls won't start melting for several weeks. But down at lower elevations, especially east of the mountains, dry conditions normally prevail. During the past 25 years February has reliably been the driest month of the year on the plains. Few major blizzards have occurred. February is sometimes called "the calm before the storm" since Eastern Plains weather often deteriorates in March.

## Interesting Facts about Colorado's Climate

Were it not for the efforts made decades ago to gather local climate data, we would still be groping to understand some of the interesting local variations we observe in Colorado. In January 1867,118 years ago, complete daily weather observations were begun at Ft. Lyon near what is now Las Animas in southeastern Colorado. Weather data from Las Animas have been collected continuously since that time making that the longest climatological record in Colorado. They have had their share of extremes over the years. Their wettest year was 1923 when 21.39" of precipitation fell. Only $2.79^{\prime \prime}$ was recorded in 1894. The highest temperature ever recorded there was $114^{\circ}$ in July 1933 while the coldest was $-32^{\circ}$ in January 1948. During 1984 their temperatures ranged from a high of $104^{\circ}$ to a low of $-29^{\circ}$ and their total annual precipitation was 11.92 .

| Date | Event |
| :---: | :---: |
| 1-5 | A cold front crossed the state producing a few inches of snow in the Northern and Central Mountains. Behind the front, weak upslope flow brought a little moisture to the Pueblo-Colorado Springs area. Colorado Springs was surprised by almost $5^{\prime \prime}$ of new snow on the $2 n d$. Dry, but cold 3-5th. Several stations had their coldest temperatures of the month including $+4^{\circ} \mathrm{F}$ at Cheyenne Wells on the 4 th , and $-17^{\circ}$ at Steamboat Springs on the 5th. |
| 6-10 | Dry, breezy, and unseasonably warm east of the mountains. Unusually warm temperatures for December were reported on the 7 th including $68^{\circ}$ at Denver and Fort Collins, $72^{\circ}$ at Pueblo and $75^{\circ}$ at Springfield. The highest temperature in the state occurred at Holly on the $10 \mathrm{th}, 76^{\circ} \mathrm{F}$. Meanwhile, moisture moved into western Colorado from the southwest on the 8 th. Vallecito Dam received nearly $10^{\prime \prime}$ of snow on the 8th and 9th. |
| 11-18 | Colder over all except southwestern Colorado with daily mountain snowfall. Thirteen inches of snow fell 11-16th at Rifle and 18" at Durango while higher elevations reported much more. Snow developed over eastern Colorado on the 12th and continued intermittently until the 15 th. Most of the area received significant snowfall with typical accumulations between 4 and 8 inches. Temporary clearing on the 14 th resulted in some of the coldest temperatures so far this winter east of the mountains such as $3^{\circ} \mathrm{F}$ at Boulder, $1^{\circ}$ at Limon and $-6^{\circ}$ at Kauffman. Then chilly and dry 17-18th. |
| 19-21 | Moisture spread into all of western Colorado producing generally light precipitation. Some local exceptions included nearly a foot of new snow at Rifle, Bonham Reservoir and near Hermit. East of the mountains remained dry with seasonal temperatures and some gusty winds on the 21 st. |
| 22-23 | No precipitation. Sunny with cold nighttime temperatures in the mountains. Alamosa dipped to $-19^{\circ}$ on the 23 rd and Silverton was $-24^{\circ}$ on the 22 nd . Taylor Park Dam claimed the month's coldest temperature with a $-42^{\circ}$ early on the 22nd. Strong downslope winds developed on the 23rd along the Front Range. Gusts near 100 mph were reported near Boulder. |
| 24 | Sharply colder over eastern Colorado as an arctic front slipped southward. |
| 25 | Cloud cover spread across Colorado on Christmas Day, but temperatures were seasonal and only a few mountain snow showers were reported. |
| 26-28 | Copious moisture moved into southwestern Colorado. Heavy precipitation was reported on the 27 th, some of it falling as rain even up to elevations of nearly 10,000 feet. Lemon Dam near Durango received 3.70" from the storm including $2.87^{\prime \prime}$ in 24 hours. Rain was reported as far north as Steamboat Springs. The Eastern Plains remained dry. |
| 29-30 | Dry and mild. |
| 31 | Light snow began in the mountains and spread to the plains during the evening causing tricky driving conditions on New Year's Eve. |

December 1984 Extremes

| Highest Temperature | $76^{\circ} \mathrm{F}$ | December 10 | Holly |
| :--- | :---: | :--- | :--- |
| Lowest Temperature | $-42^{\circ} \mathrm{F}$ | December 22 | Taylor Park Resvr. |
| Greatest Total Precipitation | $7.28^{\prime \prime}$ |  | Lemon Dam |
| Least Total Precipitation | $.02^{\prime \prime}$ |  | Brandon (Electra Lake) |
| Greatest Snowfall | $82^{\prime \prime}$ |  | Tacoma (Elect |
| Greatest Depth of Snow | $52^{\prime \prime}$ | December 28 | Bonham Resvr. |

The December precipitation pattern in Colorado was very complex. Precipitation was generally below average along the Front Range and the eastern foothills from Trinidad to the Wyoming border. The weather station at South Platte received just $0.12^{\prime \prime}$ of precipitation during the month. Bailey recorded 0.17." Most of the northern and central mountain areas were also drier than average. However, in west central and southwest Colorado heavy precipitation was observed. Parts of the San Juan Mountains, the Grand Mesa, the western portion of the San Luis Valley and scattered areas of extreme western and southwestern Colorado had more than double the average precipitation. At the same time, the Gunnison Valley got less than half of their normal December precipitation.

The Eastern Plains were generally a little wetter than average with precipitation totals mostly between 0.25 and $0.75 . "$

| Greatest |  | Least |  |
| ---: | :--- | :--- | :--- |

| Tacoma | $3.89^{\prime \prime}$ | Delta | $0.13^{\prime \prime}$ |

Precipitation for December 1984 as a percent of the 1961-1980 average.

#### Abstract

Three months into the new 1985 water year, accumulated precipitation continues to be above average over almost all of Colorado. This, in combination with above average high elevation snowpack and much above average reservoir storage, paints a good picture for surface water supplies during the coming months.

\section*{Comparison to Last Year}

Last year at this time, accumulated precipitation was also above average over all of Colorado except the lower Arkansas Valley. Record snows during November and December 1983 in the Northern and Central Mountains and the West Slope valleys helped make precipitation totals there greater than they have been so far this winter.

1985 Water Year to Date through December

| Wettest (as \% of average) |  |  |
| :--- | :--- | :--- |
|  |  |  |
| Fountain | $439 \%$ | $5.88^{\prime \prime}$ |
| Fort Carson | $408 \%$ | $6.32^{\prime \prime}$ |
| Colorado Springs | $347 \%$ | $5.79^{\prime \prime}$ |
| Holly | $335 \%$ | $5.433^{\prime \prime}$ |
| Brandon | $309 \%$ | $3.49^{\prime \prime}$ |

Driest (as \% of average)

| Williams Fork Dam | $68 \%$ | $2.34^{\prime \prime}$ |
| :--- | :--- | :--- |
| Cimarron | $72 \%$ | $2.29^{\prime \prime}$ |
| Blue Mesa Reservoir | $73 \%$ | $1.91^{\prime \prime}$ |
| Browns Park Refuge | $77 \%$ | $1.64{ }^{\prime \prime}$ |
| Red Feather Lakes | $85 \%$ | $2.30^{\prime \prime}$ |

Precipitation for October through December 1984 as a percent of the 1961-1980 average.

December temperatures were above average over most of Colorado. Parts of the Gunnison Valley and the lower Colorado and Arkansas valleys were more than 4 degrees Fahrenheit warmer than normal. Colder than average temperatures were limited to portions of the northeastern plains and some of the snowcovered mountain valleys.

Heating degree day data appear in the tables on the following pages. Degree day totals were less than average and less than December 1983 for most reporting stations. Dramatic differences were observed compared to last year (one of the coldest December's on record) east of the Continental Divide. Burlington, for example totalled 980 heating degree days compared to 1500 in December 1983. This means that heating bills east of the Divide should be much lower than a year ago.

December 1984 temperature departures from normal.

DECEMBER 1984 SOIL TEMPERATURES

Soil temperatures remained above freezing below depths of 1 foot during December thanks to several inches of snowcover before Christmas. These measurements are taken at Colorado State University beneath unirrigated sod with an open exposure.
 Fort Collins, Co December 1984

Table 1. Colorado Heating Degree Day Data through December 1984.

Fort Collins, Colorado Be523

## January in Review:

January was drier than average in most of the Colorado mountains. But in portions of western Colorado and over most of the Eastern Plains, precipitation was near or above average. Temperatures were a little cooler than average over northern and eastern Colorado, while the major southwestern valleys from Alamosa to Grand Junction were all several degrees warmer than normal. It was a fairly "gentle" midwinter month with three episodes of widespread precipitation and few occurrences of extreme temperatures and very strong winds.

A Look Ahead -- March 1985:
Temperatures begin to climb in earnest in March, especially later in the month. Daytime high temperatures average in the 50 s with lows mostly in the 20 s at locations below 6,000 feet elevation. In the high mountains and eastern foothills the warmup is more gradual. For example, at Estes Park and Climax (Fremont Pass) March temperatures average only about six degrees Fahrenheit warmer than their January temperatures. Most other areas see rises in average temperatures from January to March of at least 10 degrees.

With warmer weather comes an increase in precipitation. March is the snowiest month of the year, on the average, over all of the Eastern Plains. Winds also increase in March over most of the state. The combination of wind and snow leads to occasional blizzard conditions which can be devastating to Colorado ranchers. Fortunately, because of the warmer temperatures in March, snow usually melts within a few days east of the mountains.

Snow continues to pile up in the high mountains in March. On many of the passes $50^{\prime \prime}$ to $80^{\prime \prime}$ of new snow typically falls during the month. Some melting begins to occur at elevations below 9,000 feet, but in general, snowdepths continue to increase on into April.

New Precipitation Map is Completed:
The Colorado Climate Center has recently completed a new detailed analysis of average annual precipitation for the state. The analysis is based on data for the period 1951-1980. The results are a colored $1: 500,000$ map (approximately $43^{\prime \prime} \times 52^{\prime \prime}$ ) and an accompanying publication describing the data and the analysis. Copies of the map and the report will be available from the Colorado Climate Center. For more information please contact us at the address shown above or call us at (303) 4918545.

This new map shows clearly the complexities of our climate here in Colorado. Average annual precipitation varies from less than 7 inches near Alamosa to more than 60 inches in the mountains just east of Steamboat Springs. While there continues to be considerable year to year variations in precipitation, this new analysis indicates there are not significant trends toward either wetter or drier conditions in Colorado based on data since 1931.

| Date | Event |
| :---: | :---: |
| 1-2 | Snow continued to fall along the Front Range early on the 1 st. Then clearing and cold statewide. A few places from Boulder southward to Trinidad picked up 4-8" of fluffy new snow. Temperatures dropped to near zero over the Eastern plains early on the $2 n d$. In the mountains temperatures fell far below zero. |
| 3-6 | Mostly sunny and warmer as a large high pressure ridge dominated the western U.S. A number of cities had their warmest temperatures for the month on the 4 th and 5 th such as Greeley's $57^{\circ}$ reading on the 4 th and Las Animas' $60^{\circ}$ on the 5 th. |
| 7-11 | Upper level storm system approached Colorado from the west while cold arctic air moved southward across the Northern Plains. Snow developed over most of the state on the 8 th and was heaviest in extreme southwest Colorado. Telluride, Rico, and Mesa Verde all reported close to $12^{\prime \prime}$ of new snow 8-9th. Moderate snow fell over parts of southeastern Colorado on the 9 th. Rocky Ford measured $7^{\prime \prime}$ of new snow and the Trinidad area received at least $8^{\prime \prime}$. Skies cleared on the 10th but a little snow fell on the 11 th as another push of artic air moved across the Eastern Plains. |
| 12-18 | Except for some clouds and mountain snow showers $15-16$, it was a sunny and dry period. Pleasant days and very cold nights in the mountains throughout the period. Warming trend east of the mountains following a very cold morning on the 12 th. Occasional briel winds. Temperatures soared on the 17 th into the 50 s and a few 60 s east of the mountains. Canon City's $66^{\circ}$ reading was the warmest in the state for the month. |
| 19-22 | A strong arctic surge which delivered deathly cold temperatures to parts of the Midwest, East and South brought much colder temperatures to the eastern half of Colorado as well. From 3 to $7^{\prime \prime} \mathrm{nf}$ enow fell 19-20th from Sterling upper level storm system brought heavy snow to portions of the Northern and Central Mountains. The town of Vail received $23^{\prime \prime}$ of snow during the 4 -day period and Berthoud Pass added $26^{\prime \prime}$. The lower elevations of northwest Colorado were also hard hit. Craig totalled $10^{\prime \prime}$ and Rifle nearly a foot from the storm. |
| 23-28 | A dry period 23-26th. Sunny and cold over all but extreme southwestern Colorado on the 23 rd. Then warming a bit $24-25$ th especially east of the mountains. Clouds covered the state on the 26 th as an upper air disturbance approached. Snow began on the 27 th over most of the mountains while precipitation at lower elevations was light and scattered. Some parts of the San Juan mountains received heavy snow. Telluride and Wolf Creek pass totalled $12^{\prime \prime}$ and $23^{\prime \prime}$ of new snow, respectively. |
| 29-31 | A strong polar air mass entered colorado late on the 29th preceded by a period of snow. Up to $6^{\prime \prime}$ of wind driven snow fell on the 29th and 30th east of the mountains with lesser amounts to the west. Then temperatures plummeted to their coldest readings so far this winter. On the morning of the 31 st , temperatures were below zero over all but a few of the southwestern valleys. Examples of extremely cold temperatures included at Walden and $40^{\circ}$ at Bonham Reservoir on Grand Mesa. |

January 1985 Extremes

| Highest Temperature | $66^{\circ} \mathrm{F}$ | January 17 | Canon City |
| :--- | :---: | :--- | :--- |
| Lowest Temperature | $-40^{\circ} \mathrm{F}$ | January 31 | Bonham Reservoir |
| Greatest Total Precipitation | $3.19^{\prime \prime}$ |  | Berthoud Pass |
| Least Total Precipitation | $0.03^{\prime \prime}$ |  | Monte Vista |
| Greatest Snowfall | $69^{\prime \prime}$ |  | Wolf Creek Pass |
| Greatest Depth of Snow | $110^{\prime \prime}$ | January 31 | Wolf Creek Pass |

Precipitation, usually very sparse in January east of the Colorado Rockies, was above average over most of the plains. Totals exceeded $400 \%$ of average at both Rocky Ford and Haswell (their averages are only about 0.20"). Most of the Arkansas Valley received at least 200\% of average January precipitation. Above average precipitation was also observed in northwestern Colorado and across a small portion of southwestern Colorado from Uravan to Montrose.

Precipitation in most of the higher mountain areas was below average. From Eagle southward to Lake City less than half of the average January precipitation fell. Skiers found ski conditions to be less than ideal for much of January. The first half of the month brought very little new snow, particularly to the Central Mountain ski areas. Then, as snow improved later in the month, temperatures got just a bit too cold to make all day skiing a fun experience.

| Greatest |  |  | Least |  |
| :--- | :--- | :--- | :--- | :---: |
| Berthoud Pass | $3.91^{\prime \prime}$ | Monte Vista | $0.03^{\prime \prime}$ |  |
| Wolf Creek Pass 1E | $2.79^{\prime \prime}$ | South Platte | $0.07^{\prime \prime}$ |  |
| Pyramid | $2.20^{\prime \prime}$ | Manassa | $0.09^{\prime \prime}$ |  |
| Steamboat Springs | $2.12^{\prime \prime}$ |  | Eads |  |
| Ouray | $2.01^{\prime \prime}$ | Del Norte | $0.09^{\prime \prime}$ |  |
|  |  | Fleming 1S | $0.10^{\prime \prime}$ |  |
|  |  |  |  |  |

Precipitation for January 1985 as a percent of the 1961-1980 average.

Four months into the 1985 water year, accumulated precipitation is still above average over most of Colorado. However, with the recent dry January in much of the high country, areas with more than $150 \%$ of average precipitation have shrunk noticeably. All of eastern Colorado continues well above average although winter precipitation normally does not make up a large percentage of their total annual precipitation.

## Comparison to Last Year

The San Juan Mountains and the San Luis Valley are both a little wetter than they were last year at this time. The remainder of the mountains and Western Slope have fallen behind last year's pace. East of the mountains has so far been a little wetter than last year.

| Wettest (as \% of average) |  |  | Driest (as \% of average) |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Fountain | 412\% | $6.38{ }^{\prime \prime}$ | Blue Mesa | Reservoir | 66\% | $2.47{ }^{\prime \prime}$ |
| Fort Carson | 381\% | $6.78{ }^{\prime \prime}$ | Spicer |  | 77\% | $3.02{ }^{\prime \prime}$ |
| Holly | 341\% | $6.20{ }^{\prime \prime}$ | Browns Pa | rk Refuge | 83\% | $2.07{ }^{\prime \prime}$ |

Wettest (total precipitation)

| Lemon Dam | $15.96^{\prime \prime}$ | $166 \%$ |
| :--- | :--- | :--- |
| Berthoud Pass | $15.56^{\prime \prime}$ | $126 \%$ |
| Bonham Reservoir | $15.17^{\prime \prime}$ | $128 \%$ |

Driest (total precipitation)

| Kauffman 4SSE | $1.74^{\prime \prime}$ | $127 \%$ |
| :--- | :--- | :--- |
| Monte Vista 1E | $1.78^{\prime \prime}$ | $116 \%$ |
| Center 4SSW | $1.89^{\prime \prime}$ | $122 \%$ |

Precipitation for October through January 1985 as a percent of the 1961-1980 average.

$$

#### Abstract

January temperatures ranged from 5.4 degrees Fahrenheit below average at Trinidad to 7.4 degrees above average at Grand Junction. The majority of the state was 1 to 4 degrees cooler than average. However, the valleys of westcentral and southwestern Colorado were all warmer than normal. The polar air masses that periodically nipped eastern Colorado and the cold stagnant winter air mass which filled much of the Great Basin were unable to work their way into these portions of our state.

Heating degree day data appear in tables on the following pages. Totals were typically less than last year in western Colorado (see Gunnison for example). East of the mountains totals were quite similar to those of last January.

January 1985 temperature departures from normal.

JANUARY 1985 SOIL TEMPERATURES

Snow cover in Fort Collins during most of January helped to keep soil temperatures very stable. By the end of the month the ground was frozen only to a depth of 12". These measurements are taken at Colorado State University beneath unirrigated sod with an open exposure. These data are not representative of all locations in Colorado.

7 AM Soil Temperatures

Fort Collins, Colorado 60523

February in Review:
Very cold weather dominated Colorado in the first half of February followed by seasonal weather later in the month. Precipitation was below average over the majority of the state, particularly the mountains. Except for the severe cold early in February, major storms and weather extremes were not a big problem.

A Look Ahead -- April 1985:
The Colorado Climate Center does not make forecasts in the sense of predicting specific weather events to occur at specific times. We use historic climate information to describe the most likely or typical weather conditions throughout the year. Climate information, as such, is a very useful planning tool.

April typically brings a combination of stormy wet weather and delightful sunny spring weather to most of the state. But in the higher mountains winter persists. In parts of Colorado's central mountains, April is the wettest month of the year. Throughout the Colorado high country at elevations above about 10,000 feet winter snowdepths reach their maximum value during April. Skiers can continue to enjoy the outdoors although the snowpack becomes steadily denser and mushier. Subzero temperatures still occur but are very infrequent after the first week of the month.

At the lower elevations the chances for snow begin to decrease in April. But when it does snow, it's likely to snow hard. Last year Loveland received $188^{\prime \prime}$ of snow on April 20. Fortunately temperatures stay close to $32^{\circ}$ during snowstorms, and the snow melts quickly. The first thunderstorms of the year often begin in April -- a sure sign of coming summer. April precipitation averages 1-2" over the Eastern Plains with the greatest amounts usually in the northeast and along the Front Range. Mountain precipitation is extremely variable but generally ranges from 1-4". The western valleys are normally quite dry with less than $1^{\prime \prime}$ of total precipitation.

Typical daytime temperatures rise into the 50 s and 60 s at elevations below 7,500. But readings in the 70 s are common and even a few 80s (90s in southeastern Colorado) can occur. Near Grand Junction the last freeze of the spring usually occurs in April. Blossoming fruit orchards are a common site there. Elsewhere episodes of subfreezing temperatures usually persist into May.

## New State Record Set:

On February 1 of this year the coldest temperature ever recorded on an official National Weather Service thermometer in Colorado was observed. Maybell, in the Yampa River Valley in northwest Colorado, set the new record with a frigid temperature of $-61^{\circ} \mathrm{F}$. That same morning, Colorado's traditional ice box -- Taylor Park Reservoir -dipped to $-60^{\circ}$ to tie the previous record. A little cold weather is fine, but this is getting a bit ridiculous. A map showing official minimum temperature for February 1, 1985 is shown at the end of this report.

FEBRUARY 1985 DAILY WEATHER

| Date | Event |
| :---: | :---: |
| 1 | Clear, calm, and bone chilling cold. Zero or below at all reporting stations except for a $+1^{\circ} \mathrm{F}$ at Grand Junction. The coldest readings included $-61^{\circ}$ at Maybell, a new Colorado minimum temperature record, $-60^{\circ}$ at Taylor Park Reservoir. Numerous locations in the mountains reported temperatures below $-40^{\circ}$. It was also plenty cold on the plains such as $-25^{\circ}$ at Byers and $-16^{\circ}$ at Eads. |
| 2-7 | Very cold period 10 to 30 degrees below average. Light snow, trace to $6^{\prime \prime}$ on the 3 rd- 4 th, northeastern plains and from the mountains westward to Utah. Snowshowers continued in the mountains 5-7th as a trough of low pressure stayed over Colorado. Subzero nighttime temperatures over much of the state. |
| 8-10 | Much warmer on the 8 th as a storm system approached from the northwest. Daytime temperatures mostly in the 40 s with 50 s in the southeast. Snow began in the west late on the 8th and spread over most of the rest of Colorado on the $9 t h-10$ th. Some moderate to heavy snowfall was reported including $5^{\prime \prime}$ at Boulder and Craig, $6^{\prime \prime}$ at Aspen and more than one foot on parts of the Grand Mesa and the western San Juans. This was the only significant snowstorm of the month for a number of mountain locations. |
| 11-20 | Prolonged dry period for most of the state with persistent northwesterly winds aloft. There was just a bit of high elevation snow on the 12 th and again on the 17 th. Generally seasonal to slightly warmer than average temperatures. However, it was sharply warmer east of the mountains on the 15 th and again on the 19th and 20th accompanied by brisk winds. Denver reached $62^{\circ}$ on the 15 th, Burlington $65^{\circ}$, and Pueblo $73^{\circ}$. Kalsh and Springfield shared honors for the Colorado hot spot in February with a $74^{\circ}$. |
| 21-23 | Unsettled period as a poorly organized storm sluggishly passed south of Colorado. Periods of snow began in the southern mountains on the 20 th and 21st. By the 22nd and 23rd locally heavy snow dropped on parts of southeastern Colorado. Del Norte was surprised by $8^{\prime \prime}$ of snow from the storm. Wolf Creek Pass had much more than a foot. As the storm moved into southeastern Colorado some of the snow changed to rain and even a few thunderstorms. Strong, cold northerly winds developed. Some of the heavier precipitation amounts included $0.43^{\prime \prime}$ at Burlington and $0.60^{\prime \prime}$ at Lajunta. Near the foothills heavy snow was reported. Walsenburg got $8^{\prime \prime}$, Rye $9^{\prime \prime}$, Strontia Springs $13^{\prime \prime}$, Aguilar 14", and $20^{\prime \prime}$ on Mount Evans. |
| 24-26 | Sunny and pleasant on the 24th. Then windy and much colder again on the 25-26th as a fast moving upper air disturbance zipped across the area. Another dose of snow dropped $10^{\prime \prime}$ on Berthoud Pass, $5^{\prime \prime}$ on Boulder and $3^{\prime \prime}$ from Denver to Burlington. |
| 27-28 | Sunshine and warmer temperatures helped quickly melt some of the recent snows and bring back thoughts of spring. |

February 1985 Extremes

| Highest Temperature | $74^{\circ}$ | February 15 | Springfield 7WSW, <br> Walsh |
| :--- | :---: | :--- | :--- |
| Lowest Temperature | $-61^{\circ}$ | February 1 | Maybell |
| Greatest Total Precipitation | $-60^{\circ}$ | February 1 | Taylor Park |
| Least Total Precipitation | 0 |  | Bonham Reservoir <br> Greatest Total Snowfall |
|  | $43^{\prime \prime}$ |  | Bonham Reservoir <br> (estimated) |

The majority of Colorado was drier than average in February. Mountain areas typically received from $50 \%$ to $80 \%$ of average. The only wetter than average areas west of the Continental Divide were the northwestern slopes of the San Juans northwestward along the Uncompaghre Plateau and a small area from Rifle to the top of the Grand Mesa.

A typically complex precipitation pattern unfolded over the remainder of Colorado. In the Rio Grande Valley precipitation ranged from just a trace near San Luis to much above average near Creede. The upper Arkansas Valley was very dry while South Park had nearly double the average precipitation. East of the mountains conditions varied from almost no precipitation in extreme northeastern Colorado to more than triple the average at Limon, Burlington and Lajunta. Despite these high percentages, actual precipitation amounts were low. Most areas reported less than $0.75^{\prime \prime}$. February is normally one of the driest months of the year east of the Continental Divide.

| Greatest |  | Least |  |
| :---: | :---: | :---: | :---: |
| Bonham Reservoir | 3.03" | Kauffman 4SSE | 0.00" |
| Mount Evans | 2.44" | Brandon | Trace |
| Berthoud Pass | $2.43{ }^{\prime \prime}$ | San Luis 2SE | Trace |
| Ouray | $2.10{ }^{\prime \prime}$ | New Raymer | 0.01 " |
| Trout Lake | $1.90{ }^{\prime \prime}$ | Briggsdale | 0.02" |
|  |  | Buena Vista | 0.02" |

Precipitation for February 1985 as a percent of the 1961-1980 average.

Precipitation for the first 5 months of the 1985 water year continues above average over almost all of Colorado. However, the areas with $150 \%$ or more of average have shrunk considerably in recent months. The higher mountain areas, from which come much of Colorado's surface water supplies, are now just about average for the year. Eastern Colorado continues well above average, but much of this is still a result of a very wet October. Spring is a critical time for moisture for winter wheat and rangeland, so conditions will be monitored closely.

## Comparison to Last Year

Except for a few areas in the San Juans, the mountains and Western Slope are now significantly drier than at this time last year. Accumulated precipitation on the plains is similar to last year except in parts of the southeast which is a little wetter this year.

| Wettest (as \% of average) |  |  | Driest (as \% of average) |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Fountain | 363\% | 6.68" | Cimmaron | 59\% | 2.90" |
| Fort Carson | 336\% | $6.98{ }^{\prime \prime}$ | Blue Mesa Reservoir | 64\% | $2.86{ }^{\prime \prime}$ |
| Holly | 303\% | $6.30{ }^{\prime \prime}$ | Gunnison | 71\% | 2.61" |
| Wettest (total precipitation) |  |  | Driest (total precipitation) |  |  |
| Bonham Reservoir | $18.20{ }^{\prime \prime}$ | 125\% | Kauffman 4SSE | $1.74{ }^{\prime \prime}$ | 116\% |
| Berthoud Pass | 17.99 " | 117\% | Monte Vista 1E | $2.14{ }^{\prime \prime}$ | 122\% |
| Lemon Dam | 17.22" | 150\% | Center 4SSW | 2.24" | 126\% |

Precipitation for October 1984 through February 1985 as a percent of the 1961-1980 average.

Thanks to a very cold beginning, all of Colorado was colder than average in February. Monthly averages were as much as 8 degrees Fahrenheit colder than normal in northwestern Colorado and in the vicinity of Greeley and Longmont. Only the southernmost tier of counties in Colorado and the valleys near Gunnison and Grand Junction were within 0 to 3 degrees of average.

Heating degree day data appear in tables on the following pages. Totals were more than average statewide but were less than last year in some of the larger valleys of western Colorado.

February 1985 temperature departures from 1961-1980 averages
(degrees Fahrenheit).

FEBRUARY 1985 SOIL TEMPERATURES

The soil in Fort Collins froze to a depth of about 2 feet in early February. Much deeper frost penetration was observed in areas where the ground was not snow covered. Various parts of the state had frozen water pipe problems due to the extreme cold. The Fort Collins data are taken at the Colorado State University campus beneath unirrigated sod. The exposure is open and undisturbed.

## March in Review:

Two major storm episodes during March resulted in above average precipitation over much of the southwestern half of Colorado. East of the mountains, precipitation dwindled. Most of the Eastern Plains were much drier than average. Frequent high winds on the plains produced areas of ,blowing dust. Temperatures were generally mild.

## A Look Ahead -- May 1985:

May is the month when the mountain snowpack begins to melt in earnest and river levels rise. In a normal year, peak flows on Colorado's largest rivers will occur in June, but occasionally peaks occur earlier. Flooding usually does not occur but is a possibility in some river bottom locations when unusually warm weather persists for several days and/or heavy low-elevation rains accompany rapid snowmelt. Flooding has been a problem the last two years. With a few exceptions, the mountain snowpack is less this year and general climatic characteristics have been tracking closer to normal than the past two years.

Precipitation patterns in May are a lot different than during the winter months. Precipitation in the high mountains, much of which may still fall as snow, begins to taper off. Meanwhile, precipitation east of the mountains increases dramatically. From the northern Front Range (Denver to Fort Collins) eastward across the northeastern plains, May is the wettest month of the year, on the average. It's not at all unusual for these areas to get $3^{\prime \prime}$ or more of precipitation in May ... more than often falls in the entire November through March period combined. This characteristic of Colorado's climate helps make dryland farming possible. Close to 75\% of the average annual precipitation falls during the May-September growing season east of the mountains.

Springtime can be a bit discouraging. While May temperatures are normally quite pleasant (daytime highs average in the 70 s with lows in the 40 s over most lower elevation areas), farmers and gardeners have to contend with frosts which are likely well into the month. The eastern half of Colorado is particularly prone to periods of damp, cloudy, chilly weather in May that feel more like Seattle winter weather. And then, of course, there is that notorious threat of snow that always lingers, especially along the Front Range urban corrider. Fort Collins was belted by $27.8^{\prime \prime}$ of snow from a single storm in early May just a few years ago.

## Where Do Climate Data Come From?:

We get lots of calls from people seeking climate information who assume detailed data are collected on temperature, precipitation, wind, pressure, solar radiation, humidity, etc. for almost anywhere in the state and are publicly available at little or no cost. That would be nice -- maybe -- but it's just not true. At this time there are only 6 weather stations in Colorado staffed by National Weather Service personnel. There are a handful of airports where FAA (Federal Aviation Administration) personnel take hourly weather observations a portion of the day. Several more sites have trained observers taking scheduled observations several times daily. But the bulk of the data contained in this report and readily available to the public come from the National Weather Service's cooperative observer network. In
(continued on last page)

3-5 Deep low pressure area moved rapidly eastward across Colorado on the 3rd. Very windy and much colder. Blowing dust developed in parts of the Eastern Plains. A major snowstorm was predicted but only a few areas of significant snow fell. Berthoud Pass totalled $11.5^{\prime \prime}$ of new snow, and the Longmont-Boulder area received 5-8". Clearing and chilly 4-5th. Many locations reported their coldest temperatures of the month. Denver reported $+2^{\circ} \mathrm{F}$ on the 4 th. Subzero temperatures occurred in the mountains. Taylor Park claimed the state's coldest temperature with $-33^{\circ}$ on the 5th.

6-8 Mountain snowshowers on the 6th. Then partly cloudy and mild statewide. Strong southwesterly flow aloft began pumping moisture toward Colorado.

9-12 Significant winter storm over the Colorado Rockies. Rain and even thunderstorms fell at elevations below 9,000 feet 9-11th. Heavy wet snow above. Rainfall totals included $1.43^{\prime \prime}$ at Rifle, $1.32^{\prime \prime}$ at Cortez, and $1.17^{\prime \prime}$ at Paonia. At higher elevations, 4 -day storm totals included $1.3^{\prime \prime}$ ( $20.5^{n}$ snow) at Crested Butte, 1.77" (24.5" snow) at Berthoud Pass, and 3.16" (45" snow) at Wolf Creek Pass. East of the mountains cloudy and unseasonably warm weather prevailed 9-10th. In extreme southeastern Colorado temperatures reached the low 80 s on the 10 th for the first time this year. Colder temperatures moved in on the 11 th and snow developed from the Front Range eastward. The heaviest precipitation fell in southeastern Colorado. Campo received $0.67^{\prime \prime}$ including $2^{\prime \prime}$ of snow on the 11 th. Pueblo's $0.48^{\prime \prime}$ total included $3.2^{\prime \prime}$ of wet snow.

Sunny but chilly statewide. Subzero nighttime temperatures again in some mountain areas. Taylor Park dropped to $-25^{\circ} \mathrm{F}$ on the 14 th.

15-21 Unseasonably warm and dry period. An upper air disturbance crossed extreme southern Colorado on the 16 th and again on the 19 th producing moderate precipitation south of the San Juans. Cortez received $1.38^{\prime \prime}$ from the 2 storms.

22 Fast moving Pacific cold front raced across Colorado. A few inches of snow fell in the mountains as colder air briefly invaded the state. Very windy.

23-26 Windy, dry and unseasonably warm. Boulder and Brighton reached $78^{\circ}$ on the 25th. John Mart in Dam's $83^{\circ}$ tied Walsh for the state's highest temperature in Marchi. Severe blowing dust blown by 70 mph winds caused a chain reaction collision along I-25 near Longmont on the 26 th.

27-30 A very large winter storm system attacked Colorado. Winds in excess of 70 mph buffetted southern Colorado on the 27 th producing more blowing dust. A well developed low pressure center sat nearly stationary over the Four Corners area on the 28-29th and produced some incredibly heavy snows. Paonia, Ridgway, and Cedaredge totalled $28^{\prime \prime}$ of snow from the 4 -day storm. Meanwhile the higher mountains were buried. Silverton got $37^{\prime \prime}$ (more than $4.00^{\prime \prime}$ of water content) and Wolf Creek Pass a whopping 60". A few areas east of the Divide were also hard hit. Up to 3 feet were measured near Colorado Springs. Farther east on the plains the snow quickly diminished. A special map showing snowfall totals for this unusual storm is included at the end of this report.

Windy again. Strong northwest winds aloft brought snowsqualls to the Northern and Central Mountains -- some locally heavy amounts.

March 1985 Extremes

| Highest Temperature | $83^{\circ}$ | March 10 | Walsh, |
| :--- | :---: | :--- | :--- |
|  | $83^{\circ}$ | March 25 | John Martin Dam |
| Lowest Temperature | $-33^{\circ}$ | March 5 | Taylor Park |

| Least Total Precipitation | $00^{\prime \prime}$ |  | Fort Morgan |
| Greatest Total Snowfall | $130^{\prime \prime}$ |  | Wolf Creek Pass 1E |
| Greatest Snowdepth | $156^{\prime \prime}$ | March 29 | Wolf Creek Pass 1E |

#### Abstract

Two storm systems produced almost all of Colorado's precipitation for March. Areas skirted by those storms ended up drier than average while the remainder of the state was wet. The above average areas included most of western Colorado, the upper Arkansas Valley, South Park, the Pikes Peak-Palmer Divide area and the San Luis Valley. More than $300 \%$ of average March precipitation fell from Ridgway to Cedaredge, near Silvertion, Yellow Jacket, Rifle, Del Norte, and also in the vicinity of Eleven Mile Reservoir in South Park. On the Eastern Plains, spring precipitation is critical for dryland farming and ranching. Most of the Plains were very dry and windy in March. Portions of northeastern Colorado received less than 0.25 inches. This was in sharp contrast to the $6.00^{\prime \prime}$ and greater totals reported in portions of the San Juans.

## Greatest

| Stratton | $\mathbf{0 . 0 2 ^ { \prime \prime }}$ |

#### Abstract

Precipitation for the first half of the 1985 water year continues above average over most of Colorado. The Northern Mountains are near average for this time of year, but the remainder of Colorado's high country is above average. The dry, windy conditions in eastern Colorado had a noticeable effect on lowering accumulated precipitation departures from average.

## Comparison to Last Year

A year ago most of the state was also wetter than average. The Northern and Central Mountains, northwestern valleys, and northeastern plains were noticeably wetter than they are this year. This year, the southern and eastern slopes of the San Juans are wetter than last year.

## 1985 Water Year to Date through February

| Wettest (as \% of average) |  |  |
| :--- | :--- | :--- |
| Fountain | $318 \%$ | 8.23 |
| Fort Carson | $298 \%$ | 8.42 |
| Colorado Springs | $270 \%$ | 8.13 |

## Wettest (total precipitation)

| Wolf Creek Pass | *30.00" | $118 \%$ |
| :--- | ---: | ---: |
| Bonham Reservoir | $24.50^{\prime \prime}$ | $132 \%$ |
| Trout Lake | $22.30^{\prime \prime}$ | $158 \%$ |

Driest (as \% of average)

| Red Feather Lakes | 72\% | 3.90" |
| :--- | :--- | :--- |
| Williams Fork Resvr | $73 \%$ | $5.17^{\prime \prime}$ |
| Cimarron | $77 \%$ | $\mathbf{4 . 5 0}$ |

## Driest (total precipitation)

| Kauffman 4SSE | $1.74^{\prime \prime}$ | $81 \%$ |
| :--- | :--- | ---: |
| Briggsdale | $2.50^{\prime \prime}$ | $114 \%$ |
| Julesburg | $2.75^{\prime \prime}$ | $86 \%$ |

* Estimated, December 1984 data missing.

#### Abstract

Colorado experienced a warmer than average March. There were a few pockets with near or slightly below average temperatures such as the Meeker-Craig area, the upper Arkansas Valley, and the Silverton-Durango-Cortez area. The warmest areas were the lower Arkansas and lower South Platte valleys where some stations were more than 4 degrees Fahrenheit above average.

Heating degree day data appear in the table on the following page. Totals were less than average and less than last year (March 1984 was chillier than normal).

March 1985 temperature departures from 1961-1980 averages
(degrees Fahrenheit).

## MARCH 1985 SOIL TEMPERATURES

Deep soil temperatures are leveling off now while near surface temperatures are rapidly responding to the warm, March sun in areas where the snow has all melted. The measurements shown here are taken at Colorado State University beneath unirrigated sod with an open exposure. These data are not representative of all locations in Colorado.

MARCH 1985 SUNSHINE AND SOLAR RADIATION

| Station | Number of Days |  |  | \% of possible sunshine | average \% of possible |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | clear | partly <br> cloudy | cloudy |  |  |
| Colorado Springs | 10 | 7 | 14 | -- | -- |
| Denver | 12 | 7 | 12 | 68\% | 71\% |
| Grand Junction | 12 | 5 | 14 | 71\% | 64\% |
| Pueblo | 10 | 11 | 10 | 85\% | 75\% |

Colorado there are more than 200 stations in this network, mostly local citizens volunteering their time and effort to take basic once-daily measurements of precipitation using a standard raingage ( $8^{\prime \prime}$ diameter). About $2 / 3$ of these observers also record daily high and low temperatures. There are no fancy computers and expensive automatic weather stations. Data are transmitted by the U.S. mail, not by satellite communications. It's far from "state-of-the-art," but it still works and has worked for almost a century.

There are a growing number of sophisticated automated weather stations cropping up all over the state for a number of special purposes. The USDA's Soil Conservation Service mountain snowpack measurement network is a great example of a "high tech" data collection system for the purpose of monitoring and projecting water supplies. Many other more localized networks or single stations exist to meet special local data requirements. Evapotranspiration calculation for irrigation scheduling is another example.

No matter where we travel in this state we are likely to spot new weather stations. There is truly an avalanche of climate data being collected. Unfortunately, not all of the data being collected are readily available to you and me. No single group or agency is responsible for archiving all the weather data being collected. For that reason, and many others as well, we find that the old standby National Weather Service network -- old fashioned as it may seem -- continues to be invaluable for basic climate monitoring and analysis. It may take us a few weeks each month to get all the data in from the observers and get it assembled. But when we finally have it, it is a public information resource that is available to all of us, even if we don't have our own home computer .- and all at a very low cost.

Note: From time to time in future issues of Colorado Climate other data-gathering networks and climate information sources will be described. Also changes in existing networks will be discussed and how that might affect you and me.

Storm snowfall totals (inches) for March 27-30, 1985.

April in Review:
A week of cool, wet weather in late April brought precipitation totals above average over most of Colorado. However, it could not compensate for the unusual warmth early in the month. The entire state ended up a few degrees warmer than average.

## A Look Ahead -- June 1985:

Mountain snows finally cease in June and the snowmelt progresses full throttle. Kayakers and rafters love the raging torrents as Colorado's major rivers normally reach their peak flows in June. However, local flooding and bank erosion can be a problem.

June brings an abrupt transition from the occasional periods of cool and wet weather of spring to the low-humidity heat of summer and the traditional afternoon and evening thundershowers. The cool, damp periods often persist into mid June, but by the end of the month almost every day dawns bright and sunny. As this transition occurs, Colorado gets its share of severe weather. More tornadoes have occurred in June than in any other month. It was in early June of 1981 when the myth was broken that Colorado's Front Range cities need not be concerned about tornadoes. Thornton and other parts of the Denver metropolitan area were blasted by several tornadoes on $6 / 3 / 81$. Damaging hail storms are also a threat, especially across the Eastern Plains. In just a few seconds, entire wheat fields can be destroyed. It was just last year when millions of dollars of property damage occurred in Denver from a slow moving hail storm.

June precipitation is reliable and abundant (averaging about $3^{\prime \prime}$ ) in northeastern Colorado but typically decreases steadily toward the southwest. The Northern and Central Mountains receive only $1^{\prime \prime}-2^{\prime \prime}$ of precipitation in most Junes. In the San Juan Mountains and southwestern Colorado, June is actually the sunniest and driest month of the year. This is a convenient characteristic of our climate which helps minimize the potential flood threat. Interestingly, the past two Junes have been exceptions to this rule with both years bringing heavy June precipitation to Western Colorado enhancing existing flood problems.

June temperatures are fairly consistent year to year. Most low elevation sites begin with daytime temperatures in the 70 s early in the month rising into the 80 s and 90 s by late June. Frost is no longer a threat in June except in the mountains where temperatures on clear nights continue to drop into the 20 s and $30 \mathrm{~s}\left({ }^{\circ} \mathrm{F}\right)$.

Berthoud Pass -- Where Did You Go?:
We have some bad news to report. As of April 30, 1985, the Berthoud Pass climatological and avalanche reporting station is closed. The station has been operated during the winter months since 1950 and year-round 365 days a year since 1962 supplying detailed and very accurate information on temperature, precipitation, snow, wind, snowpack conditions and avalanche behavior. Funding for these observations has come from the U.S. Forest Service Rocky Mountain Forest and Range Experiment Station through their avalanche research program. The valuable Berthoud Pass weather data have long been unselfishly shared with and used by countless other groups with interest and concerns about high elevation climate. Termination of the Forest Service's avalanche research resulted in closing the Berthoud Pass station.
(continued on last page)

APRIL 1985 DAILY WEATHER

| Date | Event |
| :---: | :---: |
| 1-3 | Chilly morning on the 1st, then sunny, breezy and mild. Lower elevations saw temperatures in the 70 s and $80 \mathrm{~s} 2-3 \mathrm{rd}$, but cold mornings still prevailed. Taylor Park dropped to $-15^{\circ} \mathrm{F}$ on the 3 rd , the coldest in the state for April. Very strong winds and a few thundersprinkles developed on the 3rd as a Pacific front approached. Winds gusted to 69 mph at Fort Collins and 57 mph in Greeley. |
| 4-5 | Cloudy, colder and more strong winds as an upper level storm system passed Colorado. Scattered light rain and snow fell east of the mountains. Aguilar and Walsenburg picked up $5^{\prime \prime}$ of snow. Heavier snows fell in the Central Mountains such as $12^{\prime \prime}$ at Berthoud Pass and Mount Evans. |
| 6-8 | Northwesterly winds aloft. Warming west of the mountains but still chilly east. Northeastern Colorado had their coldest temperatures of the month on the morning of the 8th with readings near $20^{\circ} \mathrm{F}$. |
| 9 | Weak upper level disturbance triggered morning rain and snow showers and thundershowers from the Western Slope over the mountains onto parts of the plains. The heaviest precipitation reported was $0.68^{\prime \prime}$ at Pitkin near Gunnison. |
| 10-18 | Unusually warm period with temperatures generally 10-20 degrees above average. Temperatures soared into the 80s at many lower elevation sites $15-17$ th while in the mountains, 50 s and 60 s helped to get the snow melt started early. Several new daily temperature records were set such as $85^{\circ}$ at Greeley on both the 15 th and 16 th , and $84^{\circ}$ at Fort Collins and Denver on the 16 th . The highest temperature in Colorado was $92^{\circ}$ recorded near Wray on the 15 th and again on the 18th at Holly. Sunny and dry throughout the period until thundershowers spread northeastward across the state on the 18th. |
| 19-23 | Heavy clouds and precipitation and cooler temperatures moved into Colorado from the west and southwest. Precipitation was widespread and heavy west of the Continental Divide with snow above about 6,500 feet and rain and snow mixed below. Some totals for the storm included $1.58^{\prime \prime}$ at Grand Junction, $1.88^{\prime \prime}$ at Cortez, 2.21" at Rifle, 2.91" at Steamboat Springs ( $19^{\prime \prime}$ snow) and 4.30" at Bonham Reservoir ( $30^{\prime \prime}$ snow). Precipitation was much more spotty east of the Divide with areas like Canon City recording just a trace while La Junta got more than 1". Very strong winds occurred across the plains on the 19 th producing blowing dust in some areas. |
| 24-30 | A brief respite between storms followed by another onslaught by an even stronger, colder storm which developed quickly over Utah on the 24 th. This storm brought cold rain and snow to most of the state on the 25-26 but focused on the Front Range, northeastern plains and the upper Arkansas Valley. Heavier precipitation totals 24-26th included 1.05" at Buena Vista, 1.16" at Bailey (10" snow), 1.20" at Akron, and 1.26" at Fort Collins (3.7" snow). The storm then took an interesting route dropping south of Arizona on the 27-28th and then moving back northeastward hitting southern and eastern Colorado a second time. This time the heaviest precipitation fell in southern and southeastern Colorado. Wolf Creek Pass received $1.74^{\prime \prime}$ of precipitation ( $25^{\prime \prime}$ snow) 28-29th. Other totals included $1.28^{\prime \prime}$ at Del Norte, $1.33^{\prime \prime}$ at Parker, $1.99^{\prime \prime}$ at Rye, $2.40^{\prime \prime}$ at Palmer Lake, and $2.57^{\prime \prime}$ at Aguilar. As the storm gradually drifted out of Colorado on the 30 th, sunny and warm conditions promptly returned to western Colorado. |

## April 1985 Extremes

| Highest Temperature | $92^{\circ}$ | April 15 | Wray 1E, |
| :--- | :---: | :--- | :--- |
|  | $92^{\circ}$ | April 18 | Holly |
| Lowest Temperature | $-15^{\circ}$ | April 3 | Taylor Park |
| Greatest Total Precipitation | $5.45^{\prime \prime}$ |  |  |
| Least Total Precipitation | $0.51^{\prime \prime}$ |  | Bonham Reservoir |
| Greatest Total Snowfall | $69^{\prime \prime}$ |  | Saguache |
|  |  |  | Wolf Creek Pass IE |

April got off to a dry start, but precipitation during the latter portion of the month brought totals above average for almost all of Colorado. More than double the April average fell in several lower elevation areas of the state including North Park, the Colorado River Valley from Eagle to Grand Junction, the San Luis Valley, extreme southwestern Colorado and portions of the southeast. All of the state received appreciable precipitation, but below average totals were recorded in parts of Weld County, in east central Colorado near Burlington, in the eastern foothills from Denver north to Wyoming, along the Continental Divide from near Aspen to Grand Lake, and in a tiny area just south of Telluride.

| Greatest |  |  | Least |
| :--- | :--- | :--- | :--- |
| Bonham Reservoir | $5.45^{\prime \prime}$ | Sagauche | $0.51^{\prime \prime}$ |
| Wolf Creek Pass | $4.77^{\prime \prime}$ | Ames | $0.53^{\prime \prime}$ |
| Rye | $4.43^{\prime \prime}$ | Estes Park | $0.56^{\prime \prime}$ |
| Mount Evans | $4.27^{\prime \prime}$ | Trout Lake | $0.60^{\prime \prime}$ |
| Research Center | $4.26^{\prime \prime}$ | Gunnison | $0.63^{\prime \prime}$ |
| Aguilar |  |  |  |

Almost all of Colorado continues to be wetter than average through the first seven months of the 1985 water year. The only areas which are average or below are the extreme northwest corner, a small area in the Gunnison Valley, and a narrow band from Leadville northeastward through Grand Lake and on toward Cheyenne, Wyoming. There are still a few limited areas in south central and southeastern Colorado which have received more than double the average precipitation so far this year.

## Comparison to Last Year

Last year was also a wet year. Most of western Colorado (except for the southern slopes of the San Juans) while still above average is considerably drier than a year ago at this time. The northern Front Range and the northeastern plains are also drier than last year. The San Luis Valley, the southern half of the San Juans and the oil shale areas north of Grand Junction are all wetter than they were at this time last year.

1985 Water Year to Date through April

| Wettest (as \% of average) |  |  |
| :--- | :--- | ---: |
| San Luis 2SE | $287 \%$ | $7.11^{\prime \prime}$ |
| Fountain | $267 \%$ | $10.39{ }^{\prime \prime}$ |
| Fort Carson | $252 \%$ | $10.41^{\prime \prime}$ |

| Driest (as \% of average) |  |  |
| :--- | :--- | :--- |
| Red Feather Lakes | $67 \%$ | $5.13^{\prime \prime}$ |
| Leadville 2SW | $76 \%$ | $6.74^{\prime \prime}$ |
| Gunnison | $82 \%$ | $4.08^{\prime \prime}$ |

Wettest (total precipitation)
Driest (total precipitation)

| Wolf Creek Pass 1E | $34.00 "$ | $119 \%$ |
| :--- | :--- | :--- |
| Bonham Reservoir | $29.95^{\prime \prime}$ | $138 \%$ |
| Berthoud Pass | $26.39^{\prime \prime}$ | $112 \%$ |

| Kauffman 4SSE | $3.68^{\prime \prime}$ | $111 \%$ |
| :--- | :--- | :--- |
| Briggsdale | $3.73^{\prime \prime}$ | $107 \%$ |
| Center 4SSW | $4.05^{\prime \prime}$ | $167 \%$ |

Precipitation for October 1984 through April 1985 as a percent of the 1961-1980 average.

APRIL 1985 TEMPERATURES
AND DEGREE DAYS

April was a mild month with practically the entire state having above average temperatures. Departures from average were remarkably uniform with the majority of the state between 2 and 4 degrees Fahrenheit higher than average. This was the second consecutive warmer than normal month.

Heating degree day data appear in the table on the following page. April totals were less than average and considerably less than April 1984 (20 to 40\%). This indicates energy consumed for space heating should have been down in April.

April 1985 temperature departures from 1961-1980 averages
(degrees Fahrenheit).

APRIL 1985 SOIL TEMPERATURES

Warm April air temperatures helped to warm soil temperatures more quickly than usual. The measurements shown here are taken at Colorado State University beneath sparse unirrigated sod with an open exposure. These data are not representative of all locations in Colorado.

Berthoud Pass -- Where Did You Go?: cont inued
There are other sources of high elevation climatological data in Colorado such as the Soil Conservation Service's SNOWTEL system for remote measurements of snowpack water content. Monitoring climate in Colorado's high country is incredibly important for predicting water supplies and anticipating potential flood and droughts. Data collection in the mountains will continue and will probably even expand as water supplies become ever more precious. But even with the finest of remote automated measurement equipment it will be hard, if not impossible, to match the quality and consistency of the Berthoud Pass observations of the past 23 years. Our hats are off to Mr. Ed Henion who as conscientiously collected the Berthoud Pass weather data for that entire period. It is indeed sad to see this station go. We do hope that what has been learned about climate and avalanches at Berthoud Pass will continue to save lives.

May in Review:
The Front Range from Denver northward to Wyoming did not receive the typical heavy precipitation which often falls in May. But most of the remainder of Colorado received average to above average precipitation. Two storm systems in mid month accounted for practically all of the May precipitation. Temperatures for the month were comfortably mild with most areas about two degrees Fahrenheit warmer than average.

## A Look Ahead -- July 1985:

July is the heart of Colorado's summer and reliably the hottest month of the year. It is also the month when temperatures are most predictable, changing little from day to day. Only rarely does the monthly mean temperature deviate by more than 3 degrees from the long term average. July is also the month when the relationship between temperature and elevation is most clear and pronounced. For example, average afternoon high temperatures average in the 90 s where elevations are below 5,000 feet, average $80^{\circ}$ where elevations are near 7,500 feet, average $70^{\circ}$ near 10,000 feet, and struggle to reach $60^{\circ}$ at elevation of 12,000 feet and above. It's no wonder the mountains are a popular place to be in the summer. Tourists often are surprised (and unprepared) for the nighttime chill in the mountains. Temperatures near $32^{\circ}$ at night are not uncommon and temperatures in the mid 20 s occur on occasion. Climax reported a low of $20^{\circ} \mathrm{F}$ on July 13, 1975. At lower elevations nighttime temperatures average in the 50 s and 60 s allowing for comfortable sleep even after the hottest of days -- and their have been some hot ones. Temperatures in excess of $110^{\circ}$ have occurred at a number of eastern Colorado locations in July.

July is the month of the classic "afternoon and evening thundershowers." The pattern often works like a clock. The morning dawns crystal clear and by 10 a.m. a few puffy cumulus begin to appear, especially over the higher mountains. Between noon and 2 p.m. these clouds grow into eye-catching thundershowers which drop intense, but normally brief, showers over the mountains -- often accompanied by small, soft hail. The lightning sends hikers and mountain climbers hurrying off exposed peaks and ridges. As the afternoon progresses these storms drift eastward toward the Eastern Plains and often dissipate only to redevelop in the late afternoon as raging storms producing awesome nighttime lightning displays as they cross into Kansas and Nebraska about midnight.

While this cloud pattern holds true throughout the summer, precipitation amounts change a lot throughout the month. Early in July rainfall is quite light, especially in the western two-thirds of the state. As the month progresses, precipitation amounts often increase and storms become more numerous. The "Southwest Monsoon," warm moist winds moving northward across Mexico into the southwestern U.S., can get very well established in July and continue through much of August. This added moisture helps produce localized but very heavy rainfalls. A number of major flash flood events have occurred in Colorado during the last week of July such as the Big Thompson Canyon flood of 1976. Average July precipitation ranges from close to 1 inch in Colorado's dry western valleys to more than $4^{\text {n }}$ near Pikes Peak.

## Sad News:

On June 8, 1985 R. Wayne Light passed away. For people familiar with Steamboat Springs, the Light family has been well known for nearly 8 decades. R. Wayne Light observed the weather diligently for the National Weather Service since September 1945. His contribution to docunenting the climate of Colorado has been great. We will certainly miss him.
(National Climatic Data Center story on last page)

| Date | Event |
| :---: | :---: |
| 1-2 | Large high pressure ridge aloft over Colorado brought sunny skies and warm temperatures. |
| 3-4 | Increasing clouds but still warm -- 70s and 80 s over much of the state. Limon hit $86^{\circ} \mathrm{F}$ on the 3 rd . A few showers in western Colorado on the 3 rd . Thundershowers developed on the 4th as a Pacific cold front crossed the state. Some vivid lightning on the evening of the 4 th along the Front Range but rainfall was scattered and very light. |
| 5-7 | Cooler, especially east of the mountains. Showery as weak, moist, easterly "upslope" flow developed. Precipitation totals were mostly light but some locally heavy thunderstorms were reported. Rocky Ford received $0.75^{\prime \prime}$ and Fort Carson $1.05^{\prime \prime}$ on the 6th. Cheyenne Wells was hit by $1.12^{\prime \prime}$ from a storm late on the 7th. |
| 8-10 | Unusually warm temperatures, 10 to 15 degrees $F$ above average persisted. Rapid snowmelt produced high waters on several major rivers and tributaries. Moist southwesterly flow aloft began triggering showers over Colorado on the 10 th , especially in the west. |
| 11-14 | A pair of storm systems in close succession brought nasty weather to much of Colorado. The first storm whipped across the state on the 11 th with winds gusting to 50 mph or more in some locations. Several inches of snow fell in the mountains. The Shoshone Hydroelectric Plant near Glenwood Springs received $1.68^{\prime \prime}$ of rain on the $10-11$ th. Another low pressure area developed over the Texas Panhandle on the 12-13th and spread strong winds and very heavy rains over the eastern Colorado plains with more snow in the Colorado high country. Mount Evans received $18^{\prime \prime}$ of snow from the storm. The rain even turned to snow in parts of northeastern Colorado where up to $6^{\prime \prime}$ was reported on the 13 th. Precipitation (water content) totals for the storm varied from just a trace in parts of extreme southern Colorado to $3.05^{\prime \prime}$ at Burlington. In just 24 hours $2.72^{\prime \prime}$ fell at the small town of Joes. As the storm moved out, and skies cleared the coldest temperatures of the month occurred on the morning of the 14 th . Temperatures were generally in the 20 s and 30 s with many locations recording their last freeze of the spring. At Bonham Reservoir the mercury dipped to $+2^{\circ} \mathrm{F}$, the coldest in the state. |
| 15-22 | Chilly and unsettled spring weather. Mostly sunny on the $15 t$, then clouds, showers and afternoon thunderstorms each day. All of the state received some rain (snow in the higher mountains) but totals were heaviest from the central mountains across the eastern plains. Colorado Springs totalled 2.11" for the period and Aguilar received 2.26". Near Timpas, northeast of Pueblo, 2.05" of rain fell in a short period on the 20th including $2^{\prime \prime}$ of pea-sized hail. |
| 23-29 | A return to warmer and drier conditions. A few scattered thundershowers developed mostly 25-27th. Daytime temperatures rose into the 80 s across much of Colorado with some 90s in southeastern and extreme western Colorado. |
| 30-31 | A deep low pressure area developed over the Dakotas on the 30th. Some light showers fell, particularly in Western Colorado. Very strong, dry winds and blowing dust developed behind the cold front as it crossed the state. Holly reached $98^{\circ} \mathrm{F}$ on the 30 th, the hottest in the state in May, before the cold front arrived. |

#### Abstract

May precipitation ranged from well below average along the northern Front Range and in the southwestern and extreme southeastern corners of Colorado to much above average in a band from Uravan to Burlington through the center of the state. The scattered nature of thunderstorm activity helped complicate the pattern. In the mountains, fairly average May precipitation and warmer than average temperatures resulted in an early snowmelt. By the end of May many rivers had already reached their peak runoff flow rates except the southern and eastern slopes of the San Juan mountains where unusually high snowpack still remained.

Precipitation for May 1985 as a percent of the 1961-1980 average.

With two-thirds of the water year complete most of Colorado continues wetter than average. Sizable areas, mostly in the southern half of the state have received at least 150\% of the October through May average. The small drier than average areas are still the same as last month -- the immediate Gunnison area and a band from Leadville northnortheastward to Cheyenne, Wyoming.

## Comparison to Last Year

Last year was also a very wet year. The northern and central mountains are not nearly as wet as they were last year at this time. On the other hand, the San Juan Mountains (especially the southern slopes) are much wetter now than they were a year ago. The northern Front Range and the extreme southeastern plains are a bit drier than last year, while the San Luis Valley and the Arkansas basin are each wetter.

## 1985 Water Year to Date through May

| Wettest (as \% of average) |  |  |
| :--- | :--- | ---: |
| San Luis 2SE | $272 \%$ | $8.85^{\prime \prime}$ |
| Fountain | $246 \%$ | $14.16^{n}$ |
| Fort Carson | $228 \%$ | $14.00^{\prime \prime}$ |

## Driest (total precipitation)

| Gunnison | $4.46^{\prime \prime}$ | $80 \%$ |
| :--- | :--- | ---: |
| Alamosa | $4.51^{\prime \prime}$ | $125 \%$ |
| Monte Vista | $4.62^{\prime \prime}$ | $158 \%$ |

Precipitation for October 1984 through May 1985 as a percent of the 1961-1980 average.

For the third consecutive month Colorado experienced warmer than average temperatures. Except for a small area in the center of the state that was slightly below average, most of Colorado ended up 1 to 3 degrees Fahrenheit warmer than average.

Heating degree day data appear in the table on the following page. The May climatic data tables include cooling and growing degree days as well. The warm temperatures in May resulted in fewer than average heating degree days.

May 1985 temperature departures from 1961-1980 averages (degrees Fahrenheit).

## MAY 1985 SOIL TEMPERATURES

May soil temperatures got off to a warm start and remained favorable for seed germi nation. These measurements were taken at Colorado State University beneath sparse, unirrigated sod with an open exposure. These data are not representative of all locations in Colorado.

The National Climatic Data Center:
Nolan Doesken, Assistant State Climatologist at the Colorado Climate Center, just returned from 3 weeks at the National Climatic Data Center (NCDC). He was a participant in their State Climatologist Exchange Program.

NCDC occupies an interesting old indoor shopping mall in downtown Asheville, North Carolina, and employs a few hundred people. NCDC is a national resource for climate information. Data are received continuously from not only the U.S. but from marine locations and most foreign countries. Data are processed each month from many thousands of surface and upper air weather stations. These data are archived, summarized, computerized, published and widely disseminated.

Several periodicals are published which contain climate information for Colorado.

## Publication <br> Annual Subscription

| Local Climatological Data by city |  |
| :--- | :--- |
| (Alamosa, Colorado Springs, Denver, |  |
| Grand Junction, Pueblo) | $\$ 5.20 /$ city |
| Climatological Data -- Colorado | $\$ 9.75$ |
| Storm Data (national) | $\$ 13.80$ |
| Hourly Precipitation Data -- Colorado | $\$ 17.55$ |

Many, many other publications are available which present summarized climatic information. Most of these are described in a large report, Selective Guide to Climatic Data Sources, which is available free of charge.

For more information please contact the Colorado Climate Center or the National Climatic Data Center.

## June in Review:

The majority of Colorado was drier than average in June. Hailstorms were less numerous than in recent years, but there was a rare early summer storm which brought mountain snows and record cold to much of the state late in the month. For the month as a whole, temperatures ended up a little cooler than usual east of the mountains but well above average on the west side.

## A Look Ahead -- August 1985:

For 3 years in a row August has been unusually hot with higher than average humidity. Parts of the plains, especially the southeast, have been dry while heavy August rains have fallen in much of the mountains. But if we follow the trend of recent months, August 1985 is likely to be closer to average.

What can we normally expect in August? August is actually a lot like July. Morning sunshine followed by afternoon and evening thunderstorms is again the rule, but August storms tend to be more gentle than their early summer cousins. Damaging hail is less likely and tornadoes occur only about $1 / 3$ as often as in July. However, lots of rain can fall. The southwest monsoon circulation is typically in full swing early in the month bringing plenty of subtropical moisture northward into most of the state. Precipitation totals of more than 1" can occur from some of the slow moving early August storms. Localized flash flooding is possible. Statistically the first week of August is the wettest week of the entire summer in Colorado. As the month progresses the subtropical moisture begins a slow retreat southward, continuing to bring frequent thundershowers to the San Juan, Elk and Sangre de Cristo Mountains, but leaving the northern part of the state noticeably drier. Average August precipitation ranges from about $1^{\prime \prime}$ in extreme western and northwestern Colorado, 1-2" from the Front Range northeast toward Nebraska and in the Arkansas and Rio Grande Valleys, 2-3 inches over much of the mountains and from Colorado Springs east to Burlington, and more than $3^{\prime \prime}$ near Pikes Peak and across the San Juan mountains.

August temperatures average about 2 degrees cooler than July over the entire state. However, about 1 year in 3 August is the hottest month of the year. Similar to July, August temperatures vary little from day to day and are closely related to elevation -the higher you go, the cooler it gets. Typical afternoon high temperatures range from the low 90 s in the Arkansas and lower Colorado valleys to the 50 s and 60 s in the high mountains. While temperatures can soar into the 90 s and 100 s at lower elevations, prolonged heat waves are much rarer in August than in July. By late August temperatures are normally quite comfortable with a crisp evening chill becoming noticeable -- a hint of fall.

## How Heavy is Heavy?:

Colorado is considered to be a semiarid state. More than half of the land area in Colorado receives less than 16 inches of precipitation annually. But there have been occurrences of more rain than that in just a matter of hours. The greatest 24 -hour precipitation total at an official National Weather Service station was $11.08^{\prime \prime}$ at Holly on June 17, 1965. That same storm system produced unofficial totals in excess of 18 inches in Elbert and Prowers County. On May 30, 1935 bucket survey results suggested 24 -hour rainrall amounts of close to $24^{\prime \prime}$ near Elbert. The well-known Big Thompson Canyon flood of July 31, 1976 resulted from approximately $12^{\prime \prime}$ of rain in 5 hours at Glen Haven. Fortunately, such hea, y rainfalls occur very infrequently and are very localized.
(continued on last page)

```
JUNE 1985 DAILY WEATHER
```

1-4 Typical late spring weather -- seasonally cool with widely scattered showers. High pressure on the Great Plains strengthened on the 3rd creating moist upslope flow along the Front Range. A few very heavy thunderstorms developed with reports of hail. Fort Collins received $1.46^{\prime \prime}$ of rain in a short period. Sterling topped that with 3.11" late on the 3rd. Low clouds covered most of eastern Colorado on the 4th keeping temperatures in the 50 s and 60 s . West of the mountains skies cleared and a warming trend began.

5-8 Dry, sunny and much warmer statewide. A few very light showers fell near the mountains. Strong dry west winds developed over the state on the 8th as a deep low pressure area moved eastward along the Canadian border. Very hot temperatures for early June were felt statewide on the 8th including a $70^{\circ}$ reading at Climax, $90^{\circ}$ at Evergreen, $100^{\circ}$ at Brighton and Greeley, $102^{\circ}$ at Pueblo, $107^{\circ}$ at Las Animas, and $108^{\circ}$ at Holly -- the hottest temperature for the month. Some thundershowers developed across the plains late on the 8 th as a cold front approached bringing welcome relief from the heat.

9-12 Pleasantly cooler weather. Clouds and scattered thundershowers 9-10 from the northern and central mountains eastward across the plains. Most rainfall amounts were less than 0.25 , but Colorado Springs picked up $0.61^{\prime \prime}$ and Cabin Creek (near Georgetown) received 1.12" from showers on the 9th. Dry statewide 11-12 with chilly nighttime temperatures. It was $21^{\circ} \mathrm{F}$ at Creede and Taylor Park on the morning of the 12th.

13-16 Hot summer weather returned with dry northwesterly winds aloft. Daytime temperatures were mostly in the 80 s and 90 s except cooler in the mountains and hotter in the Arkansas Valley. Pueblo's $102^{\circ}$ on the 16 th set a new record for that day.

17-19 A cooler air mass moved into the northeastern half of the state. A few thunderstorms rumbled across southeastern Colorado. Nearly 3/4" of rain fell near Trinidad.

20-24 Mostly hot days, cool nights and dry. A fast moving cold front crossed the state on the 21 st accompanied by some strong winds, a few thundershowers, and briefly cooler temperatures in the northeast half of the state.

25-27 An unusually strong springlike storm system brought much colder temperatures and precipitation to most of Colorado beginning late on the 24th and continuing through the 26th. Rain and heavy thunderstorms turned to snow at many locations in the mountains above 8,000 feet. Southern Colorado missed the brunt of the storm but in the north heavy precipitation fell. Boulder totalled 1.26" of rain from the storm. Evergreen received 1.32", Allenspark 1.82", Nederland's total exceeded $2.35^{\prime \prime}$. Mount Evans accumulated $3^{\prime \prime}$ of new snow, but most of the mountain snow melted quickly after it fell. Skies cleared on the morning of the 27th and many new record lows were set such as $39^{\circ}$ at Fort Collins, $38^{\circ}$ at Colorado Springs, $33^{\circ}$ at Limon and $24^{\circ}$ at Yampa. Creede's $16^{\circ}$ reading was the coldest in the state.

28-30 Seasonal temperatures quickly returned. A few light thundershowers were noted on the 30 th, mostly on the eastern plains.

June 1985 Extremes

| Highest Temperature | $108^{\circ} \mathrm{F}$ | June 8 | Holly |
| :--- | :---: | :--- | :--- |
| Lowest Temperature | $16^{\circ}$ | June 27 | Creede 1S |
| Greatest Total Precipitation | $3.62^{\prime \prime}$ |  | Sterling |
| Least Total Precipitation | $0.00^{\prime \prime}$ |  | Northdale |
| Greatest Total Snowfall | $3^{\prime \prime}$ |  | Mount Evans |
|  |  |  | Research Center |

June was a dry month in Colorado. After 2 consecutive years with abnormally cool and wet Junes in the mountains, this year brought dry weather to most of Colorado's high country. Much of the eastern plains were also very dry. Large areas of eastern and southern Colorado received less than $50 \%$ of average precipitation and a number of weather stations totalled less than $0.25^{\prime \prime}$ for the month. A few places faired better. Small areas in western Colorado near Grand Junction and Meeker were wetter than average. Colorado's Front Range was also quite wet. The Nederland and Cabin Creek weather stations each received more than double their June average.

| Greatest |  |  | Least |
| :--- | :--- | :--- | :---: |
|  |  |  |  |
| Sterling | $3.62^{\prime \prime}$ | Northdale | $0.00^{\prime \prime}$ |
| Nederland 2NNE | $3.07^{\prime \prime}$ | Canon City | T |
| Cabin Creek | $2.92^{\prime \prime}$ | Hermit 7ESE | T |
| Fort Collins | $2.77^{\prime \prime}$ | Salida | $0.02^{\prime \prime}$ |
| Littleton | $2.75^{\prime \prime}$ | Pueblo | $0.10^{\prime \prime}$ |

Precipitation for June 1985 as a percent of the 1961-1980 average.

Despite a dry June, water year precipitation totals continue above average over most of Colorado. Areas with more than $150 \%$ of average precipitation since October 1, 1984 have shrunken significantly. The northeastern and southeastern corners of the state have now dropped below average to join the previously drier than average band from Leadville north-northeastward to Wyoming.

## Comparison to Last Year

At this time a year ago most of the state was wetter than average. In fact, most of the mountains and western valleys were considerably wetter than this year with the exception of the southern and eastern slopes of the San Juans. Moisture on the plains this year has been fairly similar to last year.

## 1985 Water Year to Date through June

Wettest (as \% of average)

| Creede 1S | 229\% | $15.20^{\prime \prime}$ |

Precipitation fur October 1984 through June 1985 as a percent of the 1961-1980 average.

JUNE 1985 TEMPERATURES
AND DEGREE DAYS

June temperatures in western Colorado were generally 2 to 4 degrees Fahrenheit above average. The remainder of the state was near average with some eastern plains locations as much as 2 degrees cooler than average.

> Heating degree day data for the complete $1984-85$ heating season are shown on the table on the following page. Totals for the year ended up near average with eastern Colorado tending toward slightly above average totals and western Colorado tending slightly below average. In comparison with the 1983-84 heating season, degree day totals were considerably ( $5-12 \%$ ) less than last year east of the mountains but were very similar in the rest of the state.

June 1985 temperature departures from 1961-1980 averages
(degrees Fahrenheit).
JUNE 1985 ᄃOIL TEMPERATURES

These soil temperature measurements were taken at Colorado State University beneath sparse unirrigated sod with a flat, open exposure. These data are not representative of all Colorado locations.

Colorado State University
Fort Collins, Colorado 80523

## July in Review:

Hot and dry weather in the first half of July gave way to a damp and stormy second half. Temperatures ended up fairly close to average for the month as a whole. Precipitation was above average over most of Colorado. Record breaking July rains fell in a few areas producing local flash floods and associated havoc.

## A Look Ahead -- September 1985:

September is a beautiful month in-Colorado. Sunshine is abundant statewide and precipitation is quite light. Thunderstorms become few in number and light in intensity. Mountain streams flow low and crystal clear exposing the resident trout. Chilly nights mean that stands of aspen begin their transformation into groves of gold.

September marks the end of summer in Colorado -- a season which is admittedly shorter than most of us might prefer. Daylength decreases by more than an hour during the month. With the lengthening darkness comes colder nighttime temperatures. Despite warm days with temperatures often in the 70 s and 80 s at elevations below 7,500 feet, nighttime readings drop steadily through the month. Readings in the 20 s and 30 s are to be expected by the end of September across practically the entire state (see special "Frost" article following this section).

The word "snow" returns to the vocabulary of climatologists, skiers and frustrated Californians in September. Snow doesn't occur every year but it is a possibility even at low elevations. Front Range cities have been buried on rare occasions by as much as one to two feet of wet heavy snow (with heavier amounts in the mountains). Fortunately these early snows melt quickly even in the mountains and are quickly replaced by sunshine.

September precipitation can be quite variable. Little or no precipitation has occurred in some years while a few years have been very wet. On the average, September precipitation is surprisingly uniform across the state with the majority of the area receiving between $1.00^{\prime \prime}$ and $1.50^{\prime \prime}$. Drier areas include the interior San Luis Valley, the Arkansas Valley from Pueblo to La Junta and the extreme western valleys near Grand Junction. The wettest area is the San Juan Mountains where lingering moisture from the Southwest Monsoon and an occasional dying hurricane have brought some very heavy September rains. Wolf Creek Pass averages almost $4.00^{\prime \prime}$ and once received $11.25^{\prime \prime}$ in September 1970.

## A Chilling Look at Autumn Frost:

It may seem cruel to start talking about cold weather already, but let's face it -frost is right around the corner and snow isn't far behind. Frost is defined as the feathery deposit of ice formed by the sublimation of water vapor on terrestrial objects whose temperatures are below freezing. In other words, it's the visible indication that it's downright chilly outside. Frost can form on low vegetation and rooftops when measured air temperatures are far above freezing. It is also possible, if the air is very dry, that no frost will form even when the nighttime temperature dips well below freezing.

We often talk about the first autumn frost. But since visible frost and actual air temperature don't always correlate well, climatologists prefer to use the concept of the first fall freeze. This is defined as the first occurrence after July 20 (or some other appropriate midsummer date) of an air temperature of $32.0^{\circ} \mathrm{F}$ or colder. (Official air temperature measurements are taken at a height of about 5 feet above the ground, preferably over natural grass.) The date of the first fall freeze is significant because (continued on last page)

# JULY 1985 DAILY WEATHER 

Date Event
1-3

| Comfortable summer temperatures. A few light scattered thundershowers from the |
| :--- |
| mountains eastward onto the plains, although Nunn was deluged by 1.67 " by a |
| thunderstorm on the lst. Most areas of the state experienced their coldest |
| morning temperatures of the month on the $1-3$ rd. For example, Denver had $51^{\circ}$ and |

Colorado Springs $48^{\circ}$ on the 2nd. Readings in the 20s and 30 s were observed in
the mountains including $25^{\circ}$ at Silverton and Rio Grande Reservoir on the lst and
also at Creede on the 3rd, the coldest July temperatures in the state.

July 1985 Extremes

| Highest Temperature | $108^{\circ} \mathrm{F}$ | July 7 | Las Animas <br> Lowest Temperature |
| :--- | :---: | :--- | :--- |
|  | $25^{\circ}$ | July 1 | Rio Grande Resvr |
|  |  |  | and Silverton |

Heavy thunderstorm rains over practically all of Colorado in the last half of July terminated the short term drought conditions that had developed during early summer. The entire state was wetter than average except an area in southeastern Colorado from Walsenburg southeast to the Oklahoma Panhandle, a small strip of the eastern foothills from Red Feather Lakes to Boulder and miscellaneous spots such as Lamar, Gunnison and Breckenridge. Many areas received at least double the July average including much of extreme western Colorado, a strip from Fort Collins and Greeley to Burlington, the area south of Colorado Springs and a number of small local areas such as Creede, Climax and Walden. Maybell's $2.92^{\prime \prime}$ total was more than 4 times their July normal.

| Greatest |  | Least |  |
| :--- | ---: | :--- | :--- |
| Fountain | $10.77^{\prime \prime}$ | Delta | $0.57^{\prime \prime}$ |
| Creede 1S | $7.34^{\prime \prime}$ | Montrose | $0.81^{\prime \prime}$ |
| Fort Carson | $6.59^{\prime \prime}$ | Ignacio $1 N$ | $0.83^{\prime \prime}$ |
| Burlington | $6.40^{\prime \prime}$ | Olathe 4SSW | $0.84^{\prime \prime}$ |
| Mount Evans | $6.26^{\prime \prime}$ | Cedaredge | $0.87^{\prime \prime}$ |

Precipitation amounts (inches) for July 1985 and contours of precipitation as a percent of the 1961-1980 average. The dashed line is the $150 \%$ contour.

Colorado is well on its way to completing a 4th consecutive wetter than average year. The entire state continues wetter than average except small areas on the extreme northeastern and southeastern plains and a band in north central Colorado from Breckenridge to Red Feather Lakes.

## Comparison to Last Year

Much of the Eastern Plains and the Rio Grande drainage have received more precipitation during the first 10 months of the 1985 water year than during the same period a year ago. West central and extreme southwest areas are comparably wet to a year ago. For most of the mountains, however, last year's precipitation totals were significantly higher. Grand Lake, for example, has received $16.23^{\prime \prime}$ of precipitation so far this water year compared to 23.37" last year.

## 1985 Water Year to Date through July

| Wettest (as \% of average) |  |  |
| :--- | :--- | :--- |
| Creede 1S | 261\% | $22.54^{\prime \prime}$ |
| Fountain | $245 \%$ | $25.57^{\prime \prime}$ |
| San Luis 2SE | $194 \%$ | $10.59^{\prime \prime}$ |

## Driest (as \% of average)

| Red Feather Lakes | 65\% | $9.04 "$ |

| Delta | $6.51^{\prime \prime}$ | $118 \%$ |
| Alamosa | $6.66^{\prime \prime}$ | $117 \%$ |

Precipitation for October 1984 through July 1985 as a percent of the 1961-1980 average.

July temperatures for the month as a whole rarely vary more than about 2 degrees Fahrenheit from average and this year was no exception. Temperatures across the state were almost all within a degree of average with most of eastern Colorado ending up slightly cooler than average while the western part of the state was a bit warmer than usual. The first half of the month was actually 3 to 6 degrees above average but the last half was comparably below average.

July 1985 temperatures (degrees Fahrenheit) and contours of departures from 1961-1980 averages.

JULY 1985 SOIL TEMPERATURES

Soil temperatures in the top one foot layer reflected the hot air temperatures early in July and cooler weather following. At greater depths temperatures continued their gradual summertime climb.

These soil temperature measurements were taken at Colorado State University beneath sparse unirrigated sod with a flat, open exposure. These data are not representative of all Cclorado locations.

A Chilling Look at Autumn Frost: (continued)
it affects what agricultural crops can be grown in a particular area. Some locations in the Colorado mountains can experience a freeze on any day of the year. Other locations, such as the fruit growing areas near Grand Junction typically don't experience the first fall freeze until mid or late October.

The date of the first fall freeze is a very interesting element to study. It can vary by several weeks from one year to the next and can also differ by several weeks in a given year over a surprisingly small area. Again using Grand Junction as an example, the average date of the first fall freeze at the airport is October 23; while at Fruita, just a few miles down the road in the same valley, the first freeze date averages September 30. In each of the last two years the first fall freeze has hit broad areas of the state simultaneously and abnormally early (Sep 21, 1983 and Sep 29, 1984). In both cases it brought an abrupt and economically inopportune conclusion to the agricultural growing season.

We could write a book on the subject, but for now here are a few statistics about first fall freezes at selected locations in Colorado. For more information on this subject, please contact our office.

Probabllity that the first fall freeze $\left(32^{\circ} \mathrm{F}\right)$ will occur on or before this date.

August in Review:
August was dominated by hot and dry weather over most of the state. The Southwest Monsoon. Which had been alive and well during the last 3 weeks of July, came to an abrupt halt in early August. As a result, less than half of the average August precipitation fell in most areas.

A Look Ahead -- October 1985:
Summer is but a memory as the calendar turns to October. Temperatures drop steadily throughout the month as daylength continues to shorten Early in October, temperatures remain pleasant at lower elevations. Readings often climb into the 70 s during the day and stay above freezing at night. But by the middle of the month a killing freeze normally brings an end to the growing season to even the warmest parts of the state (Grand Junction and the Arkansas Valley). By the end of the month freezing nighttime temperatures are common statewide and daytime temperatures struggle to stay above $60^{\circ} \mathrm{F}$. In the mountains it's just plain cold. At Berthoud Pass, for example, October 31 temperatures typically vary from an afternoon high of $38^{\circ} \mathrm{F}$ to a nighttime low of $15^{\circ} \mathrm{F}$. The coldest October temperature officially reported in Colorado in recent years was $-14^{\circ} \mathrm{F}$ at Antero Reservoir on October 25, 1975.

Despite the dropping temperatures, October weather conditions can be just grand. Winds normally remain light and sunshine is abundant, especially in the first half of the month. With low humidity and crisp clear air, working outdoors can be comfortable and invigorating.

Cloud patterns are noticeably different in October than during the summer. The classic towering cumulus clouds that dot the Colorado afternoon skies from May into September become rare in October are are replaced by higher, flatter altocumulus clouds. Wave formations begin to appear in these clouds near the mountains indicating strengthening westerly winds aloft -- a signal of winter's approach.

October marks the beginning of a new water year. It is the month when high elevation snows (above about 10,000 feet) begin to accumulate. It is common for the first widespread major mountain snowstorm of the winter to strike in the middle of October. At lower elevations, especially east of the mountains, Halloween is always a good guess for when the first snowstorm will hit. $0^{-}$the average, October is a relatively dry month statewide. Average precipitation totals for the month range from $0.50^{\prime \prime}-0.75^{\prime \prime}$ across the Eastern Plains to about 1" along the Front Range urban corridor to $1^{\prime \prime}-2^{\prime \prime}$ in the northern and central mountains and then back down to about $1^{\prime \prime}$ in the western valleys. The San Juan Mountains are the wettest area of the state in October averaging 2-4" of precipitation. More than $60 \%$ of the time October precipitation totals are below average. But the wet years can be very wet. Last year was a good example as many parts of Colorado received from 3 to $6^{\prime \prime}$ of precipitation. October 1972 is particularly memorable in southwestern Colorado. Many stations reported their wettest month of all time including Durango (11.79") and Vallecito Dam (12.42").

There Are Better Places To Sell Umbrellas Than Alamosa:
We almost always talk about precipitation in terms of how much falls. For most purposes, that's what matters most. But from a human comfort and enjoyment perspective what leaves a lasting impression is how often it precipitates and at what time of day. For example, even though Orlando, Florida, gets $44^{\prime \prime}$ more of rain per year than San Diego,

AUGUST 1985 DAILY WEATHER

5-8 Hot and dry. Readings in the 90 s (a few low 100 s in the Arkansas Valley) were common at low elevations, but low humidity meant bearable conditions with cool nights. Morning lows in the mountains were near $32^{\circ} \mathrm{F}$ in many locations throughout the period. Thundershowers developed ahead of an approaching cool front on the 8 th over northwestern Colorado and continued overnight over the northern mountains.

9-15 A series of cold fronts brought autumn-1ike weather to the state. Considerably cooler over parts of northern Colorado on the 9-10. Denver's high on the 9 th was only $73^{\circ}, 21^{\circ}$ cooler than the previous day. Frost formed in many mountain valleys on the morning of the 10 th. Walden dipped to $26^{\circ}$. A brief warming trend was promptly squashed by another strong cold front on the 11 th. Cold rains developed in the northern and central mountains and turned to snow above 11,000 feet. More than $0.50^{\prime \prime}$ of rain fell in several mountain locations 1112th. Taylor Park Reservoir awoke to a $17^{\circ}$ temperature on the 13 th, the coldest in the state this month. Severe thunderstorms developed in southeastern Colorado late on the 13 th and continued into the night. There were numerous reports of hail, and rainfall totals included $1.10^{\prime \prime}$ at John Martin Dam and 2.37" at Limon. Low clouds lingered in northeastern Colorado on the 14 th holding high temperatures in the 60 s and low 70 s .

16-30 A great time to be in the mountains. A large stationary high pressure ridge over the western U.S. produced scorching daytime temperatures in Colorado for most of the period. But low humidities and cool nighttime temperatures helped keep Coloradoans cool. Significant thundershower activity was limited to the southern mountains $18-21$ st and the Eastern Plains mostly $18-19$ th, although Cheyenne Wells did pick up $1.03^{\prime \prime}$ from a late night storm on the 22 nd . Temperatures were especially high $25-31 \mathrm{st}$. Numerous records were matched or broken including $95^{\circ}$ at Fort Collins and $97^{\circ}$ at Denver on the 26 th, and $90^{\circ}$ at Buena Vista and $101^{\circ}$ at Pueblo on the 31 st. The $108^{\circ}$ reading at Wray on the 31 st was the hottest temperature in the state for August. Temperatures even climbed into the 70 s as high up as 11,000 feet. Forest and grassland fire danger once again soared and several small fires were ignited.

August 1985 Extremes

| Highest Temperature | $108^{\circ} \mathrm{F}$ | August 31 | Wray |
| :---: | :---: | :---: | :---: |
| Lowest Temperature | $17^{\circ}$ | August 13 | Taylor Park Rsvr |
| Greatest Total Precipitation | 4.52" |  | Creede 1S |
| Least Total Precipitation | $0.00{ }^{\prime \prime}$ |  | Dinosaur National Monument (and other stations) |
| Greatest Total Snowfall | $0.5^{\prime \prime}$ |  | Climax |

#### Abstract

In sharp contrast to July, August was considerably drier than average over most of Colorado. A large number of official reporting stations received less than $25 \%$ of the August average. The only areas which received above average precipitation were a band from northeast of Colorado Springs to Limon, a tiny area near Creede and Hermit, and parts of Baca, Prowers, Bent and Las Animas counties in southeastern Colorado.

\[

\]

Precipitation amounts (inches) for August 1985 and contours of precipitation as a percent of the 1961-1980 average.

Areas with below average precipitation for the first 11 months of the 1985 water year are spreading in northern portions of Colorado. However, the majority of the state continues above average, and water supplies this year have been very good.

Comparison to Last Year
The 1985 precipitation has not kept pace with the 1984 water year. This year has been noticeably drier in the northern and central mountains and in the eastern foothills. Areas that are wetter than last year include some of the eastern central plains, the Pikes Peak area, and the Rio Grande Valley.

1985 Water Year to Date through August

| Wettest (as \% of average) |  |  |  |
| :--- | :--- | :--- | :---: |
| Creede is | $254 \%$ | $27.06^{\prime \prime}$ |  |
| Fountain | $208 \%$ | $26.74^{\prime \prime}$ |  |
| Parachute | $182 \%$ | $20.55^{\prime \prime}$ |  |

Wettest (total precipitation)

| Wolf Creek Pass 1E | $42.85^{\prime \prime}$ | $109 \%$ |
| :--- | :--- | :--- |
| Bonham Reservoir | $38.42^{\prime \prime}$ | $128 \%$ |

| Center 4SSW | $7.52^{\prime \prime}$ | $125 \%$ |
| Alamosa | $7.57^{\prime \prime}$ | $109 \%$ |

Precipitation for October 1984 through August 1985 as a percent of the 1964-1980 average.

August temperatures on the whole were above average over most of Colorado. The Western Slope and southeastern plains were the warmest areas, relative to average, with August temperatures two to three degrees Fahrenheit warmer than usual. Low humidities and below average cloud cover during August resulted in a larger than average diurnal temperature range. Daily high temperatures were more than four degrees above average at many locations, but nighttime temperatures were actually a little cooler than usual over most of Colorado. Low temperatures below $50^{\circ}$ occurred surprisingly of ten across the northeastern plains. In the mountains, nighttime freezes occurred more often than usual.

August 1985 temperatures (degrees Fahrenheit) and contours of departures from 1961-1980 averages.

AUGUST 1985 SOIL TEMPERATURES

Soil temperatures in the top 3 feet of soil have reached their summer peaks and are now cooling down. Deep soil temperatures lag several weeks behind and will continue to rise on into autumn.

These soil temperature measurements were taken at Colorado State University beneath sparse unirrigated sod with a flat, open exposure. These data are not representative of all Colorado locations.

Table 1. Colorado Heating Degree Day Data through August 1985.

There Are Better Places To Sell Umbrellas Than Alamosa: (continued)

California, at 8 a.m. you have the same chance of getting wet at either place ( $4 \mathrm{p} . \mathrm{m}$. is quite a different story).

How does Colorado stack up with the rest of the country? During an average year, Denver receives measurable precipitation ( $\geq 0.01$ inches) in 367 hours or $4.2 \%$ of the total number of hours in a year. San Diego, known for year round sunshine and climatic uniformity, averages just 171 hours of precipitation (2.0\%). St. Louis comes in with 462 hours (5.3\%), New York City totals 702 hours ( $8.0 \%$ ) and Portland, Oregon, gets dribbled with rain for 723 hours in an average year (8.3\% of the time).

Colorado gets its fair share of variety right here within the State borders. The Colorado Climate Center has compiled statistics for more than 80 locations where hourly precipitation has been measured to the nearest 0.01" for at least 20 years. Based on frequency of precipitation, the southeastern Colorado plains are the driest in the state receiving measurable precipitation less than $2 \%$ of the time (less than San Diego). Frequencies increase as we approach the mountains. The Climax weather station on Fremont Pass receives measurable precipitation $8.3 \%$ of the time. So right here in our own state we see the full range of extremes experienced by major population centers across the entire U.S.

The frequency and timing of precipitation is very complex. In the summer most precipitation in Colorado falls during the afternoon. In the winter this pattern reverses, especially in the mountains. The most likely time to receive snow in many mountain locations is between 2 and $4 \mathrm{a} . \mathrm{m}$. Many factors work together to produce the precipitation patterns we experience. They are all a part of our fascinating climate.

The following table shows the frequency of measurable precipitation for selected locations in Colorado. Some seasonal information is presented for a few sites.

## September in Review:

Frequent shower activity and an early siege of record-breaking cold and snow characterized September. For the month as a whole temperatures were below average statewide, and most areas of the state were wetter than normal.

A Look Ahead -- November 1985:
Few people choose November as their favorite month. Climate is not the sole reason for this, but it may play a part. Long nights, shortening days, dropping temperatures, more frequent clouds, snow and blustery winds over the mountains and the occasional return of the "brown cloud" of visible pollution over many of the Front Range cities let everyone know that winter is here to stay. This may sound drab, dreary and depressing, but compared to many parts of the country, Colorado's Novembers aren't too bad.

The Continental Divide becomes a distinct line of climatic demarkation during the winter. Cloudiness normally increases along and west of the mountains as the strengthening late autumn jet stream carries Pacific moisture toward Colorado. But even so, Grand Junction still receives $63 \%$ of the possible sunshine. November precipitation west of the Divide averages 1 to $2^{\prime \prime}$ over most areas but with the higher mountain areas receiving more (typically 2-4") and the lower valleys less ( 0.5 to $1^{\prime \prime}$ ). As the upper level westerly winds of winter increase, moisture east of the Continental Divide becomes more scarce. East of the Divide most areas average less than $1^{\prime \prime}$ of precipitation with several areas of the northeastern plains, the San Luis Valley, South Park and an area from Pueblo. Colorado Springs and Limon southeastward to near Lamar averaging less than $0.50^{\prime \prime}$. Some rain falls at low elevations early in November, but the majority of precipitation statewide falls as snow. Mountain snowpack builds slowly in November but 2 to 4 feet of snow may be on the ground above 11,000 feet by the end of the month.

Temperatures drop sharply through the month. Daily highs still average in the mid and upper 50s early in November at most low elevation locations with a few days in the 60s and even the 70 s , but by the end of the month averages are in the mid 40 s with a few days at or below $32^{\circ}$. Nighttime temperatures average in the 20 s early in the month, but by late November temperatures in the teens become common. Mountain temperatures are, of course, colder with daytime highs mostly in the 30 s and 40 s dropping to the 20 s and 30 s late in the month. Lows average in the teens with warmer temperatures occurring during stormy periods but much colder readings occurring with clear, dry weather. Subzero temperature occur infrequently at low elevations (below 6,000 feet) in November, but higher areas near the mountains have seen extreme cold such as Fraser's -37 on November $22,1957$.

November weather is generally not too extreme. Other than the typical wintry weather in the higher mountains, the threatening situations to look out for are "downslope" windstorms along the Front Range and occasional widespread snowstorms such as the preThanksgiving storm of 1979 and the post Thanksgiving storm of 1983. These storms occur infrequently but are actually more likely in November than in December, January or February.

## 1985 Water Year Wrap-Up: (Special Feature)

See pages 4 and 5.

## SEPTEMBER 1985 DAILY WEATHER

A nearly stationary low pressure area aloft lingered near the West Coast throughout the first 15 days of September producing a steady flow of air from the southwest over Colorado. This southwesterly flow brought abundant subtropical moisture into Colorado. The dip in the jet stream began shifting eastward in mid September and gradually moved over Colorado during the last 10 days of the month. As it did, it pulled down cold arctic air which clashed with the warm moist air it was replacing. This produced plenty of clouds and precipitation culminating in a significant late-month snowstorm.

| Date | Event |
| :---: | :---: |
| 1-4 | A weak cold front brought clouds and cooler weather to northeastern Colorado. The rest of the state was unseasonably hot and humid with thunderstorms each day, some of them heavy. |
| 5-9 | A clearer, drier period except on the 7th when an upper air disturbance brought widespread clouds, cold rain (in excess of $0.50^{\prime \prime}$ in some locations) and high mountain snows to much of southwestern and central Colorado. |
| 9-11 | A large high pressure area over the northern plains pushed cool air into eastern Colorado. Widespread rain and low clouds were east of the mountains on the 11th. At the same time a surge of moisture accompanied an upper level disturbance into southwestern Colorado. Most of the state ended up with moderate precipitation but a few local areas were really drenched. Most of the San Juan Mountains received at least $1^{\prime \prime}$ of rain. Wolf Creek Pass totalled 2.12" and Creede received 3.19". Canon City measured $1.02^{\prime \prime}$ while the Trinidad area received from $1^{\prime \prime}$ to $2.50^{\prime \prime}$. |
| 12-14 | Clearing and dry. The first freeze of autumn in some areas in and near the mountains. |
| 15-18 | Sunny, breezy and warm east of the mountains but the mountains and Western Slope received widespread rainfall on the 15 th and on the 18 th. Some rainfall amounts were again heavy with Creede and Wolf Creek Pass totalling 3.59 and $4.46^{\prime \prime}$, respectively, for the period. |
| 19-23 | Summer bowed out less than gracefully as a strong cold front crossed the state. Shower activity daily, especially in and near the mountains. Snow in the mountains on the 22 nd spread into the lower foothills. Climax and Mount Evans both picked up $10^{\prime \prime}$ of snow. Clearing 23rd with the first freeze of the fall over much of northeastern Colorado. |
| 24-25 | Another cold front brought strong winds and some mountain snows. |
| 26-30 | Briefly warmer on the 26 th and 27 th before a strong cold front rudely banged into Colorado. Snow developed over most areas from the mountains eastward to Kansas 28-29th as temperatures plummeted into the 20s. Snowfall totals included $4^{\prime \prime}$ at Fort Collins, 7" at Fort Morgan, Evergreen and Akron, $9^{\prime \prime}$ at Denver and 11" at Boulder. Even Las Animas totalled 1". Temperatures hovered near or below freezing on the 29th and dropped to record shattering lows in the teens and low 20s across most of the Eastern Plains on the 29th and 30th. Red Feather Lakes reported $-2^{\circ} \mathrm{F}$ on the 30 th for the state's coldest temperature. All told, it was the coldest siege of September weather ever to hit eastern Colorado in recorded |
|  | history. | the coldest siege of September weather ever to hit eastern Colorado in recorded history.

## SEPTEMBER 1985 PRECIPITATION

Colorado precipitation in recent months has been on a roller coaster ride of alternating very wet and very dry periods. September was another wet one with much of the state well above average and many stations receiving measurable precipitation on 10 to 20 days. The wettest areas included the southern and central mountains and a narrow band northeastward from South Park to Julesburg. Most of these areas received at least double their average September precipitation. Creede was deluged by nearly $13^{\prime \prime}$ of rain, 10 times their average. As usual, parts of the state were missed by the storms. A small area in northwestern Colorado near Craig, Maybell and Meeker was below average along with a sizable portion of southeastern Colorado.

Precipitation amounts (inches) for September 1985 and contours of precipitation as a percent of the 1961-1980 average.

Most of Colorado was wetter than average for the recently completed 1985 water year (October 1984-September 1985). Much of west central and southwestern Colorado was 40 to $60 \%$ above average. Based on past records, this much precipitation falls in one year an average of only once in 10 to 30 years. Also excessively wet compared to average was the area from central Arapahoe County southward to just east of Walsenburg, including the cities of Pueblo and Colorado Springs. The Fountain weather station southeast of Colorado Springs totalled $28.79^{\prime \prime}$ for the year shattering their previous record year, 1965.

There were a few areas with near and slightly below average precipitation for the water year. These included portions of the central and northern mountains from Leadville to Granby, much of the northern Front Range and the perimeter counties of northeastern Colorado. A narrow band in southeastern Colorado including Walsenburg, Trinidad, Lamar and Springfield was also near or slightly below average.

## 1985 Water Year Statistics

| Wettest (as \% of average) |  |  |  |
| :--- | :--- | :--- | :---: |
| Creede 1S | $341 \%$ | $40.03^{\prime \prime}$ |  |
| Fountain | $204 \%$ | $28.79^{\prime \prime}$ |  |
| Ridgway | $178 \%$ | $22.51^{\prime \prime}$ |  |

Wettest (total precipitation)

| Wolf Creek Pass 1E <br> Mount Evans | $52.70^{\prime \prime}$ | 122\% |
| :--- | :--- | :--- |
| Research Center <br> Creede 1E | $41.26^{\prime \prime}$ | $136 \%$ |
|  | $40.03^{\prime \prime}$ | $341 \%$ |

Driest (as \% of average)

| Red Feather Lakes | 73\% | $12.45^{\prime \prime}$ |
| :--- | :--- | :--- |
| Redwing 1WSW | $75 \%$ | $10.53^{\prime \prime}$ |
| Gunnsion | $79 \%$ | $7.67^{\prime \prime}$ |

Driest (total precipitation)

| Gunnison | $\mathbf{7 . 6 7}$ | 79\% |

| Browns Park Refuge | $8.78^{\prime \prime}$ | $108 \%$ |
| Alamosa | $\mathbf{8 . 9 0 ^ { \prime \prime }}$ | $115 \%$ |

Precipitation for the complete 1985 Water Year (October 1984 through September 1985) as a percent of the 1961-1980 average.

1985 Water Year Wrap-Up (Continued)

The 1985 water year began with a cold, stormy October and ended with a similarly (but not as extreme) cold and wet September. Sandwiched between was a mild and fairly dry late fall and early winter, followed by a period of severe cold in late January and early February. The months of March through May were warmer than average across all of Colorado with above average precipitation across most of the mountains and western valleys and adequate moisture over most of the Eastern Plains. The summer months, June, July and August, were warmer than average across southern and western Colorado and slightly cooler than average in the northeast. The summer was unusually dry with less thunderstorm activity than normal. However, a barrage of storms in the last half of July offset much of the dryness of the rest of the summer.

Precipitation for the May through September growing season was actually quite close to average over most of the state. Significantly wetter than normal conditions were reported over west central Colorado, the San Juan Mountains and a few small areas east of the mountains. Drier than average conditions were noted in parts of Weld, Huerfano and Las Animas counties and in a small portion of northwestern Colorado.

Special Note: The 1985 Water Year was the 4th consecutive wetter than average year over the majority of the state. Consecutive wet years, especially in the mountains where most of our surface water supplies originate, should be viewed as a blessing and not taken for granted. This has been a very unusual period in Colorado's recent history and is not likely to continue much longer.

Growing season (May-September 1985) precipitation as a percent of the 1961-1980 average.
AND DEGREEDAYS

Early September temperatures were warmer than average. Unseas onably cold temperatures in the last 10 days of the month more than offset the early warmth resulting in below normal temperatures for the entire state. Most of the state ended up 2 to 4 degrees Fahrenheit colder than average. The Grand Junction area and a few locations in the Central Mountains were even colder. Only southeastern Colorado remained near average for September. This was the third consecutive year with abnormally early freezing temperatures across most of Colorado's agricultural areas. This year's record-shattering cold wave in late September even damaged some coldhardy crops.

September 1985 temperatures (degrees Fahrenheit) and contours of departures from 1961-1980 averages.

SEPTEMBER 1985 SOIL TEMPERATURES

Soil temperatures near the surface normally drop steadily during September. This year the drop was particularly sharp. Early cold does not foretell abnormally deep frost penetration later in the winter.

These soil temperature measurements were taken at Colorado State University beneath sparse unirrigated sod with a flat, open exposure. Tinese data are not representative of all Colorado locations.

Table 1. Colorado Heating Degree Day Data through September 1985.
