Abstract

As part of a multi-year project to inventory the entire state, we trapped mammals in the orders Insectivora, Chiroptera, and Rodentia in three latilong blocks in southwest Colorado during the Spring and Summer of 2005, and the Spring of 2006. We placed Sherman traps in 66, gopher traps in 11, pitfall traps in 19, and mistnetted 44 locations with the goals of confirming the presence of and better delineating the ranges of rare species. Notable findings included the capture of two state-historic subspecies of pocket mice (*Perognathus* spp.) that had not been documented in Colorado for over 20 years, and the confirmation of the presence of other taxa in numerous locations. These additional targets that were documented included: *Neotoma albigula brevicauda*, *Myotis californicus*, *M. thysanodes*, *M. yumanensis*, and *Antrozous pallidus*. Significant effort was put forth to document two species, Stephens' woodrat (*Neotoma stephensi*) and Allen's big-eared bat (*Idionycteris phyllotis*), that have not yet been confirmed in Colorado as well as the dwarf shrew (*Sorex nanus*) which is a rare shrew in Colorado. We were unsuccessful in documenting these species, but possible locations of *Idionycteris phyllotis* were documented based upon audible vocalizations.

Introduction

As a group, the distributions of small mammals have been well studied in Colorado (Warren 1910, 1942; Lechleitner 1969; Armstrong 1972; Fitzgerald *et al.* 1994), yet the geographic ranges of some species are not well understood. Gaps in information exist because many mammalian groups are understudied. Because the ecology and distribution of some species are poorly understood, it is difficult to determine the best strategies for conservation. A better understanding of small mammal distributions throughout Colorado will allow for the development of more comprehensive and successful conservation strategies.

The goals of this project are twofold. Of primary interest is the understanding of distributions of rare small mammals in Colorado. This includes evaluating what species occur in the State as well as better defining their ranges. Secondly, we would like to address the lack of surveys for small mammals in general. Aside from those focused on federally listed species (*e.g.*, *Zapus hudsonius preblei*), distributional surveys for small mammals are rare.

The mammalian taxonomic orders addressed in this study are Insectivora (shrews and moles), Chiroptera (bats), and Rodentia (mice, rats, voles, gophers, squirrels, prairie dogs, *etc.*). These orders are often underrepresented in survey efforts. The less-common species and subspecies have been prioritized to better focus survey effort as well as inform conservation strategies, but it is expected that this survey effort will help to clarify the ranges of many small mammals.

In order to meet the primary objective of clarifying the distribution of lesser-known small mammals in Colorado, Schorr and Siemers (2001) developed a protocol that focuses on a prioritized list of species, but also allows for the sampling of mammals in major habitats throughout the State. This protocol focuses on rare or understudied species and surveys are focused on habitat types within latitude/longitude blocks. See Methods below for further discussion.

Methods

The methods outlined below follow those described by Schorr and Siemers (2001) with a few exceptions. The most notable exception is the use of Ecological Systems developed by NatureServe (Comer *et al.* 2003a; Comer *et al.* 2003b) as opposed to the habitat categories developed within the survey protocol (Schorr and Siemers 2001). While both classifications are based upon the Colorado Gap Analysis Project (GAP), the Ecological Systems, referred to as “habitats” throughout this report, have been developed for the entire state of Colorado and provide a consistent framework within which the mammal project can be based. Fieldwork for this project occurred during Spring and Summer 2005, and Spring 2006. This timeframe is referred to as a “year” of effort throughout the report to reflect the protocol established previously (Schorr and Siemers 2001; Siemers *et al.* 2003; Siemers and Schorr 2006).

Study Area

Using latitude/longitude (latilong) blocks (1° latitude by 1° longitude), Colorado was sectioned into ten approximately-equal parts (Schorr and Siemers 2001). The study area for the current effort includes three latilong blocks in the southwest corner of Colorado (Southwest Group) (Figure 1).

Figure 1. Three latilong blocks of Year 3 (Southwest) study area.

The study area was further broken down into 33 habitat types based on Ecological Systems. Nine of these 33 habitats (bolded in Table 1 below) represented over 80% of the total study area. Each of these nine habitats made up greater than 5% of the study area. (Table 1; Figures 2-4).

Selection and Prioritization of Small Mammal Taxa

To assess which small mammals are valid taxonomic entities, we used the *Suggested Interpretation of Mammalian Taxonomy in Colorado for Use in Ranking and Tracking* (Wunder *et al.* 1998). From this assessment, species and subspecies were selected based on their relative rarity and the amount of information known about them. The two rarity scales used in assessing a species' or subspecies' rarity were the Colorado Division of Wildlife's (CDOW) Colorado Vertebrate Ranking System (COVERS) and the Colorado Natural Heritage Program's (CNHP) Biodiversity Tracking and Conservation System.

All taxa that are currently tracked by CNHP from Insectivora, Chiroptera, and Rodentia were included in the study. CNHP zoologists have determined species or subspecies tracking status based on several factors. Those factors include: 1. the animal's rarity based on its geographic range, habitat specificity, and local population size [based on Rabinowitz (1981)]; 2. whether the animal is evolutionarily distinct or isolated; 3. whether the animal is endemic to Colorado; and 4. whether there is sufficient information to document declining population trends (CNHP 1999). For this year's survey effort, twenty species and subspecies were determined to be of greatest conservation concern and information need (Table 2).

Table 2. Small mammal taxa addressed in Year 2.

Scientific name	Common name	CNHP Rank*	Fine-filter (F), Coarse-filter (C), or Opportunistic (O)	Years to be surveyed
Order Insectivora				
<i>Sorex nanus</i>	dwarf shrew	G4 S2	C	1 – 5, 7, 8

Inventory methods

1. Field survey techniques:

- Rodent live-trapping: Small mammal fauna were sampled using Sherman live traps (approximately 8cm x 8cm x 24 cm). Traps were baited with rolled oats and a ball of polyfil (polyester fiberfill) was placed in each trap to provide warmth. Traps were set in the evening (after 5 pm) and checked the following morning before 11 am. Traps were set out of direct sunlight to prevent overheating. All animals were identified immediately during the checking of traps. Sometimes measurements of external physical features, such as weights and lengths, were taken. Individuals that were not new or notable location records or needed for positive identification were released.
- Pitfall trapping: Pitfall traps were used to capture insectivores and other small mammals, which are frequently under-sampled in live trapping. Pitfall traps are 4-liter, number-10 coffee cans or similar-sized plastic paint buckets buried flush in the ground along natural features in the area. These traps were inspected to retrieve and identify any animals that were captured. Individuals that were not new or notable location records or needed for positive identification were released.
- Mist netting: Mist nets were used to capture bats. Mist nets are the most effective means of capturing flying bats in open areas. Mist nets are constructed of fine synthetic fibers supported by a lattice-work of braided nylon. The frame and trammels of the net are supported to form a capture area perpendicular to the ground with 4 or 5 long horizontal pockets of fine mesh (Wilson *et al.* 1996). The nets were monitored constantly to prevent bats from becoming completely ensnared and to prevent damage to the nets. Bats were removed, identified, and measurements of key features are taken. Individuals that were not new or notable location records or needed for positive identification were released. Before being released, bats were allowed to recover from stress imposed during handling.
- Fossorial mammal trapping: Pocket gophers (*Thomomys*, *Geomys*, and *Cratogeomys*) were captured using Victor gopher traps. These traps are commonly used for gopher

control throughout the state of Colorado. Gopher sign (active mounds, tunnels) dictated how many and where traps were set.

- e. Visual identification: Not all species or subspecies required the collection of voucher specimens to document their presence in an area. Visual observations of mammals or their sign can assist in delineating a species or subspecies range. For instance, prairie dogs can be identified to species without taking specimens and documentation of the extent of the mounds seen in an area can be used to delineate prairie dog colonies.

2. Survey protocol:

Each mammal on the prioritized list for year three of the survey (Table 2) was evaluated to determine how its distribution could be delineated most appropriately. We used a method based on scale-dependent (fine or coarse) surveying. We used the following characteristics to determine which mammals would be surveyed using coarse-filter methods and which would be surveyed using fine-filter methods: 1. the size of the animal's distribution in Colorado [based on Fitzgerald *et al.* (1994)]; 2. how well-defended this distribution is (how many locations have been documented to determine the current distribution). A third category for surveying (opportunistic) was included for taxa that are not of the highest priority for this project, but additional information would be beneficial for assessing conservation action.

- i. Fine-filter surveying: For mammals that have a fairly restricted distribution in Colorado (*e.g.*, pocket gopher subspecies), we used a targeted effort to better determine their distribution and their presence within that distribution. This involved surveying within and at select limits of their current known distribution. As the mammals were detected at the outer limits of the distribution, additional survey took place further and further from the edge of the distribution until the species or subspecies of interest could no longer be detected.
- ii. Coarse-filter surveying: The distributions of some of the small mammals on the prioritized list are difficult to assess. For some taxa there are few data on their current distribution (*e.g.*, *Perognathus flavus*), while others are more widely distributed, but there are relatively few records within their distributions (*e.g.*, most shrews and bats). Logistically, it would be difficult to adequately delineate the distribution of these species or subspecies. For these taxa (and others that may not be apparent), surveys were conducted in major habitat types within the study area in an attempt to obtain new location records. For the coarse-filter animals that have better-described habitat associations (*e.g.*, *Perognathus flavus*), we conducted coarse-filter surveys in similar habitat types throughout the study area.
- iii. Opportunistic surveying: Several rare taxa have well-delineated distributions (*e.g.*, *Cynomys leucurus*) and this project did not focus its efforts on these mammals. However, data regarding distribution were collected as these species were encountered.

Results & Discussion

Fossorial Mammal Trapping

Trapping for pocket gophers took place in 11 locations and in 7 different Ecological Systems (Table 3; Figure 5). Locations represent 2-10 gopher traps set for one day. Detailed information on museum specimens can be found in Appendix I.

Mistnetting

Mistnetting for bats was performed at 44 different locations and in 13 different habitats (Table 5; Figure 7). Most locations represent a single mistnetting effort (night) using multiple (2 or 3) nets. Detailed information on museum specimens can be found in Appendix I.

Sherman Live-trapping

Sherman traps for rodents were set in 66 locations and in 16 different habitats (Table 6; Figure 8). Effort at each location varied from approximately 50 to 200 trapnights. The majority of locations represent an effort of 75-125 traps set for one night. Detailed information on museum specimens can be found in Appendix I.

Fine-filter Species

Plains pocket mouse (*Perognathus flavescens caryi*)

One subspecies of plains pocket mouse (*P. f. caryi*) occurs within the study area in the Dolores, San Miguel and Gunnison River Valleys and was formally known as *P. apache caryi* (Armstrong 1972). The Colorado Natural Heritage Program (CNHP) ranked this subspecies as a state-historic element (SH), indicating that this subspecies had not been observed for over 20 years. Prior to this study, the last specimen recorded in CNHP's database for this subspecies in Colorado was taken in 1982.

We found *Perognathus flavescens caryi* in one location in Inter-Mountain Basins Big Sagebrush Shrubland.

Figure 9. Pocket mouse capture locations.
○ = *Perognathus flavus hopiensis*; □ = *P. flavescens caryi*

Silky pocket mouse (*Perognathus flavus hopiensis*)

Perognathus flavus hopiensis is another pocket mouse subspecies that was considered a state-historic (SH) subspecies by CNHP prior to this study and, according to CNHP's database, had not been documented in Colorado since 1977. This silky pocket mouse subspecies occurs in the extreme southwestern corner of the state in Montezuma and La Plata counties (Armstrong 1972).

Perognathus flavus hopiensis was found in three locations in the study area. Two of these locations were less than 1 km apart and trapped in May and September of 2005. These locations were approximately 5 km from the specimen location from 1977. The other location at which we found this subspecies of silky pocket mouse, which was approximately 7 km from the other two, was trapped in June of 2006. All three new locations occurred within Inter-Mountain Basins Mixed Salt Desert Scrub habitat.

Further survey effort focused on pocket mice (*Perognathus* spp.) in the survey area is warranted. Although we had greater success this year than in previous years (Siemers *et al.* 2003; Siemers and Schorr 2006) capturing pocket mice, overall captures were still quite low.

White-throated woodrat (*Neotoma albigula brevicauda*)

Two subspecies of white-throated woodrat (*Neotoma albigula*) occur within the study area. *N. a. brevicauda* occurs in Mesa, Montrose, and San Miguel counties and *N. a. laplataensis* occurs in the southwestern corner of Colorado in Dolores, Montezuma, La Plata, and Archuleta counties (Armstrong 1972). Only *N. a. brevicauda* was considered a target subspecies during this study because of its comparatively restricted range within the state.

Neotoma albigula brevicauda was captured in five locations in the following habitats: Southern Rocky Mountain Pinyon-Juniper Woodland, Colorado Plateau Pinyon-Juniper Woodland, Rocky Mountain Subalpine – Montane Riparian Woodland and Shrubland, and Inter-Mountain Basins Montane Sagebrush Steppe. The capture location in Dolores County falls between the two subspecies' ranges (Armstrong 1972) and may represent a zone of intergradation between *N. a. brevicauda* and *N. a. laplataensis*.

Based upon the relative ease with which *N. a. brevicauda* was captured, the status of this subspecies appears to be relatively stable. When middens were found in suitable habitat, captures of this subspecies were typically made.

Figure 10. *Neotoma albigula brevicauda* capture locations.

Other Fine-filter Species

There were two species that are yet to be documented within Colorado for which we spent considerable effort looking. Stephens' woodrat (*Neotoma stephensi*) and Allen's big-eared bat (*Idionycteris phyllotis*) both occur in adjacent states and likely occur in the southwest corner of Colorado.

Stephens' woodrat is known from San Juan County, New Mexico within a mile of the Colorado border (Harris 1963 cited in Armstrong 1972). Suitable habitat was found south of Durango on the Southern Ute Indian Reservation, but permission from the Southern Ute Indian Tribe was not obtained to trap at that location. One woodrat specimen was taken from Archuleta County approximately 15 km from the location near the Colorado border in New Mexico, however this individual was identified as a Mexican woodrat (*Neotoma mexicana*) (Appendix I).

Allen's big-eared bat is a species restricted to Mexico and the southwestern United States (Czaplewski 1983) and has been captured in Utah near the Colorado border (Armstrong 1974; Black 1970). Allen's big-eared bat is one of the few bat species in the western United States that emits echolocation calls that are audible to humans. Audible "clicks" were heard at numerous locations while mistnetting that are thought to be unique to Allen's big-eared bat (Figure 12), but no captures were made to verify the identification of these individuals.

Figure 11. Mistnetting locations at which distinctive audible clicks were heard, indicating the possible presence of Allen's big-eared bat.

Coarse-filter Species

California myotis (*Myotis californicus*)

The California myotis was captured at two different locations in the study area. One location was in Mesa County in Colorado Plateau Pinyon-Juniper Woodland habitat and the other was in Montezuma County in Inter-Mountain Basins Mixed Salt Desert Scrub.

Fringed myotis (*Myotis thysanodes*)

The fringed myotis was captured in five locations in the study area and in four different habitats. These habitats included: Colorado Plateau Pinyon-Juniper Woodland, Inter-Mountain Basins Big Sagebrush Shrubland, Rocky Mountain Subalpine Mesic Meadow, and Inter-Mountain Basins Mixed Salt Desert Scrub.

Figure 12. Bat capture locations. □ = *Myotis californicus*; ○ = *M. thysanodes*

Yuma myotis (*Myotis yumanensis*)

The Yuma myotis was captured at one location in San Miguel County in Colorado Plateau Pinyon-Juniper Woodland habitat.

Pallid bat (*Antrozous pallidus*)

The pallid bat was captured at five locations in Montrose, San Miguel, and Montezuma counties in Inter-Mountain Basins Big Sagebrush Shrubland, Southern Rocky Mountain Pinyon-Juniper Woodland, and Inter-Mountain Basins Mixed Salt Desert Scrub habitats.

Figure 13. Bat capture locations. ○ = *Antrozous pallidus*; □ = *Myotis yumanensis*

Shrews

The dwarf shrew (*Sorex nanus*) was a coarse-filter target for this year's study area (Table 2). In Colorado the dwarf shrew occurs primarily in the mountainous regions of the state at elevations above 5,500 feet (Fitzgerald *et al.* 1994), and its range overlaps the interior margin of this year's study area. Despite considerable effort in apparently suitable habitat, no captures of the dwarf shrew were made during this year's effort.

In a previous study of shrew habitats and capture methods by Brown (1967), the dwarf shrew was readily captured in pitfall traps placed in rockslide habitats. We placed 22 pitfall traps in a rockslide/talus slope for over two weeks and did not capture any shrews. Further survey effort in rockslide and talus slope habitats is warranted to determine how widespread the use of these habitats is throughout the range of the dwarf shrew.

One shrew specimen captured during this year's effort has been tentatively identified as *Sorex preblei*, based upon relative size of the third and fourth unicuspid (U3 > U4) and its relatively small size. This individual was captured in San Juan County in Rocky Mountain Subalpine – Montane Riparian Woodland and Shrubland habitat and was captured with *S. cinereus* and *S. monticolus* (Table 4; Appendix I). This could be an important finding as there are very few *S. preblei* specimens from Colorado; however, identification cannot be confirmed until further verification of this individual's identity is made.

Shrews remain one of the least-known groups of any vertebrates in Colorado in terms of both where they occur and what their population trends may be. Continued effort to better understand the distribution and population status of shrews in Colorado is needed.
