APPENDIX A

PRESSURE DATA

Note: Pressure coefficients are defined in Section 4.3.

Pressure tap designation is explained in Figure 3.

WD	TAP	CPMEAN	CPRMS	CPMAX	CPMIN

APPENDIX B

MEASUREMENT AND ANALYSIS OF ACCELERATION

APPENDIX B

MEASUREMENT AND ANALYSIS OF ACCELERATION

This appendix deals with the acceleration of a given floor--say the top floor--of a tall building. It is assumed that the motion occurs entirely within the horizontal x-y plane. The motion of an arbitrary two-dimensional body is indicated in Figure B-1. At any given point P(x,y) the acceleration vector $\underline{a}$ can be resolved into two orthogonal components of magnitude a_x and a_y:

$$\underline{a} = a_x \underline{i} + a_y \underline{j} \tag{B.1}$$

Two accelerometers would be both necessary and sufficient to determine the acceleration at this given point. Since the body can rotate about the point 0 (its own z-axis), however, the two accelerometers are insufficient to determine the acceleration at any other point; that is, a_x, a_y, and therefore $\underline{a}$ are functions of x and y as well as of time.

The <u>entire</u> acceleration field can be specified using three variables $\ddot{x}$, $\ddot{y}$, and $\ddot{\theta}$, as shown in Figure B-2:

$$\underline{a}(x,y) = \ddot{x}\,\underline{i} + \ddot{y}\,\underline{j} + r\ddot{\theta}\,\underline{t} \tag{B.2}$$

where

$\underline{a}(x,y)$ = total acceleration at a point P(x,y) having distance $r = x^2 + y^2$ from center of twist 0

$\ddot{x}$ = acceleration due to translation of body along x-axis

$\ddot{y}$ = acceleration due to translation of body along y-axis

$\ddot{\theta}$ = angular acceleration (in radians/sec^2) due rotation of body about z-axis (assumed center of twist)

$\underline{t}$ = unit tangent vector = $-(y/r)\,\underline{i} + (x/r)\,\underline{j}$

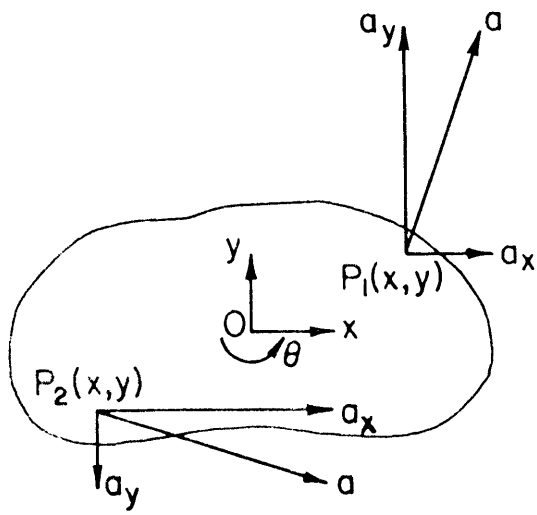

Figure B-1. Total Acceleration Vector at Various Points on a Two-Dimensional Body

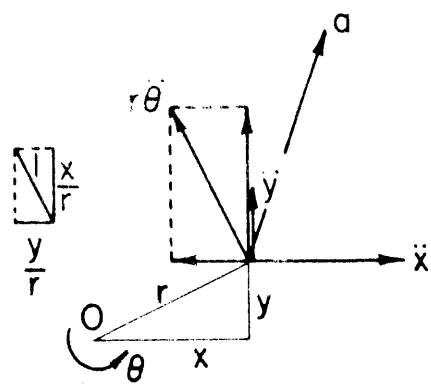

Figure B-2. Total Acceleration Vector as the Sum of Three Components in the X-Y Plane

This equation can be easily expanded to the form of Equation (B.1), which clearly indicates that a_x is due to both $\ddot{x}$, $\ddot{\theta}$, and a_y is due to both $\ddot{y}$, $\ddot{\theta}$:

$$\begin{aligned}\underline{a}(x,y) &= \ddot{x}\,\underline{i} + \ddot{y}\,\underline{j} - (y/r)(r\ddot{\theta})\underline{i} + (x/r)(r\ddot{\theta})\underline{j} \\ &= (\ddot{x}-y\ddot{\theta})\underline{i} + (\ddot{y}+x\ddot{\theta})\underline{j} \\ &= a_x\,\underline{i} + a_y\,\underline{j}\end{aligned}$$

Now the magnitude of the acceleration is given by

$$\begin{aligned}a^2 = a_x^2 + a_y^2 &= \ddot{x}^2 - 2y\,\ddot{x}\,\ddot{\theta} + y^2\,\ddot{\theta}^2 + \ddot{y}^2 + 2\,x\,\ddot{y}\,\ddot{\theta} + x^2\,\ddot{\theta}^2 \\ &= \ddot{x}^2 + \ddot{y}^2 + (x^2+y^2)\,\ddot{\theta}^2 - 2\ddot{\theta}(\ddot{x}y-x\ddot{y})\end{aligned}$$

Statistics of the acceleration are determined by time-averaging this equation over a period T as follows:

$$\begin{aligned}\overline{a^2} = \frac{1}{T}\int_o^T |a|^2\,dt &= \frac{1}{T}\int_o^T \overline{(\ddot{x}^2 + \ddot{y}^2 + r^2\ddot{\theta}^2 - \ddot{\theta}(\ddot{x}y-x\ddot{y})}\,dt \\ &= \overline{\ddot{x}^2} + \overline{\ddot{y}^2} + \overline{r^2\ddot{\theta}^2} + x\,\overline{\ddot{y}\ddot{\theta}} - y\,\overline{\ddot{x}\ddot{\theta}}\end{aligned}$$

If the rotational motion is assumed to be independent of the translational motions, then the cross-correlations vanish, resulting in

$$\sigma_a = \sqrt{\overline{a^2}} = \sqrt{\sigma_{\ddot{x}}^2 + \sigma_{\ddot{y}}^2 + \sigma_{r\ddot{\theta}}^2} \qquad (B.3)$$

Reduction to SDOF System Using Modal Analysis

A common analytical model of a tall building, suitable for the analysis of dynamic horizontal loading, is to consider it a chain of lumped masses, connected in series by beam elements. Displacements in the x-direction, y-direction, and rotations about the (vertical) z-axis are considered independently. For each of these components, the structural "frame" model will have n degrees of freedom, corresponding to the side-sway (or rotation) of each floor or lumped mass point. The system may then be described by an n x n stiffness matrix [k], with an "input" n-component load vector {P}, and an "output" n-component displacement vector {x}.

In a static system, these are related by the familiar equation

$$\{P\} = [k]\{x\}$$

When the loading varies with time and height, however, a complete description would be

$$[m]\{\ddot{x}\} + [c]\{\dot{x}\} + [k]\{x\} = \{P\}$$

where [m] is the matrix of lumped masses, [c] is a matrix of damping coefficients, and {x} and {P} are now functions of time. This represents a system of n simultaneous equations, which would be difficult to solve even if {P} could be determined. If a transformation to a system of "generalized coordinates" is applied, these simultaneous equations are simplified to n uncoupled equations. Each equation corresponds to one of the generalized coordinates, ξ_i, which also has an associated natural frequency f_i and mode shape $\{\phi\}_i$. Furthermore, due to the frequency distribution of wind energy, almost all of the excitation occurs in the fundamental mode associated with the lowest

natural frequency. It is then only necessary to consider the first of the generalized coordinate equations, which appears as

$$m^*\ddot{\xi} + c^*\dot{\xi} + k^*\xi = P^* \tag{C.1}$$

where

$$m^* = \{\phi\}^T[m]\{\phi\}$$

$$c^* = \{\phi\}^T[c]\{\phi\}$$

$$k^* = \{\phi\}^T[k]\{\phi\}$$

$$P^* = \{\phi\}^T\{P\}$$

These are referred to as the generalized mass, damping, stiffness, and load, respectively. This governing equation is that of a conventional single-degree of freedom system. The solution of the system, ξ, is related to the actual system by

$$\{x\} = \xi\{\phi\} \ . \tag{C.2}$$

It can be shown that the natural frequency of the system is

$$f_o = \frac{1}{2\pi}\sqrt{k^*/m^*} \ . \tag{C.3}$$

A further key property of tall structures is that the mode shape may be approximated by a straight line, that is $\phi_i = \alpha z_i$ or $\{\phi\} = \alpha\{z\}$. Since the magnitude of a mode shape is arbitrary, α may be taken as unity. The generalized mass then becomes

$$m^* = \{z\}^T[m]\{z\} = \Sigma m_i z_i^2 \tag{C.4}$$

which is approximately the mass moment of inertia, I, about the base. The generalized load is

$$P^* = \{z\}^T\{P\} = \Sigma P_i z_i \tag{C.5}$$

which is the moment about the base, M. The displacement vector is

$$\{x\} = \xi\{z\}, \text{ or } x(z) = \xi z$$

which shows that ξ is the rotation of the structure (which remains a straight line by assumption) about its base, θ. By analogy to the SDOF system the generalized stiffness k^* is equivalent to a simple rotational stiffness k_θ. Introducing the critical damping ratio,

$$\zeta = \frac{c}{c_{cr}} = \frac{c^*}{c^*_{cr}} = \frac{c^*}{2\sqrt{k^*m^*}}$$
$$= 2m^*\omega_o$$

where $\omega_o = 2\pi f_o$ is the natural circular frequency, the governing equation (C.1) may be rewritten as

$$I\ddot{\theta} + 2I\zeta\omega_o\dot{\theta} + k_\theta\theta = M(t) \qquad (C.6)$$

Solution of the Governing Equation Using Random Vibration Theory

Equation (C.6) is most easily solved in the frequency domain when the loading $M(t)$ is random in time, since an arbitrary function of time can be described by a superposition of sinusoidal functions. For such a harmonic function at frequency f,

$$M(t) = M_o\sin(2\pi ft + \psi),$$

the solution is (in magnitude, ignoring phase)

$$\theta(t) = \frac{1}{k_\theta}\,|H(f)| \cdot M(t)$$

where the frequency response function $H(f)$ is defined as

$$|H(f)| = \frac{1}{\sqrt{[1-(f/f_o)^2]^2 + (2\zeta f/f_o)^2}}$$

In terms of the spring load M, which is equal to

$$M = k_\theta\theta,$$

the solution is simply

$$M(t) = H(f) \cdot M(t)$$

Note that $M(t)$ and $M(t)$ are both moments, and that $H(f)$ is dimensionless. If the driving frequency f is near the structure's natural frequency f_o, and the damping ratio ζ is low, this function is an amplification factor describing a condition known as resonance. $M(t)$ is properly described as an externally applied base moment, whereas $M(t)$ is an internal or "response" base moment. Note that if $M(t)$ were externally applied to the structure and a static analysis performed, the calculated response (displacement or internal forces) would be the same as the actual response due to the real fluctuating load $M(t)$. Thus $M(t)$ is also referred to as a "static equivalent load."

When the loading $M(t)$ is random in time, its statistical description as a superposition of harmonics is its "power spectral density," denoted $S_M(f)$. The response moment is then also described as a power spectral density, $S_M(f)$. The general result of random vibration theory is the relationship between these two, which is simply

$$S_M(f) = |H(f)|^2 \cdot S_M(f) \qquad (C.7)$$

The relating function $|H(f)|^2$ is just the square of the frequency response function, and is referred to in general as the transfer function:

$$|H(f)|^2 = \frac{1}{\sqrt{[1-(f/f_o)^2]^2 + (2\zeta f/f_o)^2}} \qquad (C.8)$$

This particular transfer function is also referred to as the "mechanical admittance."

The principal usefulness of the power spectral density of a function is that its variance may be computed as the area under the spectrum:

$$\sigma_M^2 = \int_o^\infty S_M(f)df \tag{C.9}$$

The response is expected to be normally distributed (Gaussian) statistically, and thus can be completely described by its variance σ_M^2 and mean value $\bar{M}$ (note that the mean response $\bar{M}$ is equal to the mean load $\bar{M}$). Since the structural damping is very low, the response is also "narrow band," i.e., it can be loosely described as vibration at a single frequency f_o with randomly varying amplitude. Each cycle of vibration has a maximum and negative "peak" value associated with it. It is this series of peaks which are of interest insofar as structural design for strength or stiffness is concerned. It can be shown that these peak values obey a Rayleigh probability distribution, which is easily obtained from σ_M^2. The expected value, variance, etc. of these peaks could be easily found from the Rayleigh distribution. What is more desirable, however, are statistics describing the <u>largest</u> peak which is likely to occur. Such an analysis is beyond the scope of this review, and the following result is simply stated:

$$\hat{M} = \bar{M} + g\sigma_M \tag{C.10}$$

Here $\hat{M}$ is the expected value of the largest peak M occurring during a duration T of the loading M. The so-called "peak factor" g is calculated as follows [3]

$$g = \mu + \frac{.5772}{\mu} \tag{C.11}$$

where $$\mu = \sqrt{2\ell n\nu T} + \frac{\ell n\sqrt{2\ell n\nu T}}{\sqrt{2\ell n\nu T}}$$

$$\nu = f_o\sqrt{8\zeta}$$

Nomenclature

$[c]$	Damping matrix
c^*	Generalized damping
f_o	Natural cyclic frequency of fundamental mode
g	Peak factor
$\|H(f)\|^2$	Mechanical admittance (transfer function)
I	Mass moment of inertia of fundamental mode approximated by straight-line shape
$[k]$	Stiffness matrix
k^*	Generalized stiffness
k_θ	Rotational stiffness of fundamental mode approximated by straight-line shape
M	Resultant base moment of externally-applied wind load
$\hat{M}$	Response (internal, static equivalent) base moment
$[m]$	Mass matrix
m^*	Generalized mass
m_i	Mass lumped at floor i
$\{P\}$	Vector of P_i
P_i	Resultant force of wind load acting at floor i
P^*	Generalized load
$S_{(\ )}(f)$	Power spectral density of ( )
$\{x\}$	Vector of floor displacements
$\{z\}$	Vector of z_i
z_i	Height of floor i
ζ	Critical damping ratio
θ	Rotation of fundamental mode approximated by straight-line shape
ξ	Generalized coordinate
$\sigma_{(\ )}$	Standard deviation (fluctuating rms) of ( )

$\sigma^2_{(\ )}$	Variance of ( )
$\{\phi\}$	Mode shape
ψ	Phase angle
ω_o	Natural circular frequency
$\bar{(\ )}$	Temporal mean of ( )
$\hat{(\ )}$	Expected peak value of ( )
