Abstract

Sampling for aboveground and belowground biomass of primary producers, litter, invertebrates, and decomposers was conducted at 10-day intervals on a grazed and protected area on the Jornada site. During the 1970 growing season, precipitation was below-average for the season, and most of the biological activity occurred during the major rainy period in the last week of July. Peak standing crop of aboveground biomass of primary producers occurred in mid-August on the grazed area and early September on the ungrazed area.

Invertebrate populations peaked on both grazed and ungrazed areas in late July. Insect numbers were consistently higher on the grazed area than on the ungrazed area. The order Acarina contained the greatest numbers of individuals. Decomposer biomass also peaked following the rains in late July.

INTRODUCTION

Sampling for above- and belowground biomass of primary producers, litter, invertebrates, and decomposers was conducted on the Jornada Site during 1970. The basic design for the study was to compare an area grazed by cattle which was temporarily protected by a five-acre enclosure in 1970 with one which was completely protected from cattle grazing. The protected area would be classed in high, good, or excellent condition, based on the Soil Conservation Service System of range condition classification, while the grazed area would be in fair condition. The sampling design included two replications for each treatment. The temporary enclosure will be moved to another, similar area for the 1971 season.

PRIMARY PRODUCER STUDIES

Methods

The plot shape used for aboveground biomass sampling was a rectangle 6.655 cm by 762.000 cm. Plants were clipped at ground level, and all separations were made in the field. Each species was collected separately. Ten quadrats were clipped and ranked for each replication for each treatment, while 100 quadrats were ranked only according to procedures of the dry weight rank method. Litter was collected by hand from each of the clipped quadrats. All samples were dried at 70°C before being weighed. The litter samples were ashed to correct for soil contamination.

Belowground biomass was sampled using a core 7.62 cm in diameter. A soil core was taken at the end of each clipped quadrat. Soil cores were taken each time aboveground samples were collected. Cores were taken to the caliche layer, which was usually at about 30 cm. Each core was

divided into 10 cm segments. These samples were dried at 65°C for 24 hours, after which they were gently agitated on a 500 micron screen. The portion which remained on the screen was placed in a seed separation blower which was operated at two speeds to separate the fine root hairs and then the large ones. Any large roots remaining in the residue were easily visible and removed by hand. All belowground material was again dried at 65°C, and then weighed and ashed at 550°C for 40 hours. Crowns were included in belowground samples.

Results

Peak standing crop of aboveground material was 138 g/m² on the ungrazed area, compared to 78 g/m² on the grazed area (Tables 1 and 2). The peak occurred earlier on the grazed area than on the ungrazed area, possibly because of the ability of the annuals on the grazed area to respond more quickly to the one storm period in late July than the perennials on the ungrazed area. *Bouteloua eriopoda* and *Yucca elata* contributed most of the aboveground biomass on the ungrazed area, while *Salsola kali* and *Gutierrezia sarothrae* were the most important species on the grazed site (Table 3).

Belowground biomass varied considerably throughout the growing season from one sampling period to another (Table 4). During the early part of the growing season, there was no consistent difference between the grazed and ungrazed area, but later in the season, belowground biomass on the grazed area apparently exceeded that on the ungrazed area (Table 5). During most sampling periods, belowground biomass was higher in the 0-10 cm depth than for the other two depths.

The weight of litter samples was quite variable from one sampling period to the next, with the standard deviation often exceeding the mean (Table 5).

Litter weight on the ungrazed area probably exceeded that on the grazed area for the whole season.

INVERTEBRATE STUDIES

Methods

A grid was established on each replication of the ungrazed and grazed area, and the intersection of the grid lines was marked by a stake. Each stake was 25 ft from the nearest stake. At each sampling period, five stakes were randomly selected in each replication for sampling. Thus, there were 10 plots sampled at each sampling date per treatment.

The sampling method used was the standard quick trap utilized by investigators at the other comprehensive sites. The traps and tripods are set out over the randomly selected stake 24 hours before the samples are to be taken. The traps are released by a 30 ft rope, and litter and insects are removed with a D-vac. When all samples in a replication have been collected, they are stored in an ice chest. After the samples have been collected, they are brought to the lab at New Mexico State University and placed in Berlese units. Excess sand is separated from the sample by using a Kimwipe tissue paper on the screen as a baffle.

After separation, the insects are counted and classified to family, or to some lower category where possible, and dried for 24 hours at 60°C and weighed. All samples are being stored for further analysis.

Results

Peak numbers of insects occurred on both grazed and ungrazed area on July 30 (Table 6). At this time, there were nearly twice as many insects on the grazed area as on the ungrazed area. There were greater numbers of insects on the grazed area compared to the ungrazed area at all dates. Incomplete data on insect biomass indicate that differences between grazed and ungrazed areas may not be so clear cut, although peak biomass also occurred on July 30 on both areas (Table 7).

The order Acarina contained the greatest number of insects on both areas on most dates (Table 7). Other orders which were represented by fairly high numbers were the Hymenoptera, Homoptera, and the Coleoptera. There were surprisingly few grasshoppers (Orthoptera).

DECOMPOSER STUDIES

Soil samples were removed on a monthly basis from June through December 1970. The sampling times were coordinated as much as possible with the core sampling conducted by those involved with productivity studies. Procedures employed followed the recommendations for plate count studies as summarized by Dr. Francis Clark in his 19 November 1969 letter to Comprehensive Network microbiologists. One deviation from the recommended procedure had to be made, and that was the division of soil cores into profile intervals. Due to a caliche layer located just below 30 cm, sufficient soil was removed to test, and it was referred to as the 30 to 50 cm level instead of the 40 to 50 cm depth.

Early in June, cellulose and blue stem litter bags were constructed and buried. The information distributed on 20 November 1969, concerning the

cellulose decomposition study at the Pawnee Site, was used as a guide for both types of litter to be buried.

The bacterial and fungal plate counts are summarized in Table 8. Bacterial numbers determined throughout the study period were basically the same. When a total was made of the numbers in the entire profile, a few more bacteria were observed in the July sampling. Similarly, the fungal numbers were generally the same during the seven months of examination. Again, a few more fungi were observed during the October examination than the other months, when the entire profile was totalled.

Due to a shortage of muffle furnaces, the cellulose and blue stem decomposition determinations have not been completed and cannot be included in this report.

Belowground Biomass Data

Belowground biomass data collected in 1970 at the Jornada Site is Grassland Biome data set A2U0028. Data were collected on form NREL-03. A sample data form and a listing of the field data follow.

GRASSLAND BIOME
U.S. INTERNATIONAL BIOLOGICAL PROGRAM
FIELD DATA SHEET - BELOWGROUND BIOMASS

DATA TYPE

- 01 Aboveground Biomass
 - 02 Litter
 - 03 Belowground Biomass
 - 10 Vertebrate - Live Trapping
 - 11 Vertebrate - Snap Trapping
 - 12 Vertebrate - Collection
 - 20 Avian Flush Census
 - 21 Avian Road Count
 - 22 Avian Road Count Summary
 - 23 Avian Collection - Internal
 - 24 Avian Collection - External
 - 25 Avian Collection - Plumage
 - 30 Invertebrate
 - 40 Microbiology - Decomposition
 - 41 Microbiology - Nitrogen
 - 42 Microbiology - Biomass
 - 43 Microbiology - Root Decomposition
 - 44 Microbiology - Respiration

SITE

- 01 Ale
 - 02 Bison
 - 03 Bridger
 - 04 Cottonwood
 - 05 Dickinson
 - 06 Hays
 - 07 Hopland
 - 08 Jornada
 - 09 Osage
 - 10 Pantex
 - 11 Pawnee

TREATMENT

- 1 Ungrazed
 - 2 Lightly grazed
 - 3 Moderately grazed
 - 4 Heavily grazed
 - 5 Grazed 1969, ungrazed 1970
