ABSTRACT

Livetrapping on grids at two Network Sites on the northern Great Plains
(Osage and Cottonwood) provides the basis for estimates of small mammal standing
crop biomass density at three times during the growing season.

Small mammal densities at Osage were low in May, but increased from then until October. Wet weight and dry weight (in parentheses) biomass density was calculated as 38.5 (11.6) g/ha in May, 348.9 (104.7) g/ha in August, and 1600.0 (480.0) g/ha in October. This increase in biomass density resulted primarily from increasing numbers of Sigmodon hispidus, which increased from 0 (0) g/ha to 192.8 (57.8) g/ha to 1372.8 (411.8) g/ha during the three collecting periods, and secondarily from those of Microtus ochrogaster, which increased from 7.0 (2.1) g/ha to 109.0 (32.7) g/ha to 118.7 (35.6) g/ha during the three collecting periods.

Small mammal densities at Cottonwood were relatively low at all three collecting periods. Biomass density estimates were 37.9 (11.4) g/ha, 379.0 (112.9) g/ha, and 225.3 (67.6) g/ha, respectively for the June, July, and September samples. The higher biomass density in July relative to that in September resulted largely from the number of thirteen-lined ground squirrels (Spermophilus tridecemlineatus) on the grids in July. Biomass density for ground squirrels alone was 280.5 (84.2) g/ha at that period. Ground squirrels were not captured on the grids in either June or September.

Lagomorphs on both sites were censused by means of roadside transects. A survey of disturbance caused by small mammals was also conducted at each site. Results and limitations of these studies are discussed. Demographic trends of small mammals on both sites through 2 years (1970 and 1971) are also considered.

INTRODUCTION

The purpose of the studies reported herein was to survey the status of and provide population estimates of small mammal populations on two second-order sites in the Comprehensive Network program of the IBP Grassland Biome project. During the period 16 May to 19 October 1971, field parties from the University of Kansas and the University of Minnesota studied and collected mammals during three collection periods on two Comprehensive Network Sites, Osage and Cottonwood (see Fig. 1), in the northern and central plains. Details of work accomplished at these sites in 1971 are reported herein. The composition of field crews varied through the summer, with the following persons involved: D. M. Armstrong, E. C. Birney, D. Byman, A. Cadena, R. J. Cinq-Mars, R. S. Hoffmann, R. P. Lampe, R. M. Timm, and M. D. Tuttle. Mammals collected have been catalogued in the Museum of Natural History at the University of Kansas and the Bell Museum of Natural History at the University of Minnesota. Some amphibians and reptiles were collected on Comprehensive Network Sites and are catalogued in the Bell Museum's collections (Appendix I).

METHODS

Grids

Grids were a square of 12×12 stations (144 total). The interval between each station in the rows and columns was 15 m, giving the grid an area of 2.76 ha. Each grid station was semi-permanently marked with a wooden stake, numbered with its row and column position. Grids trapped in 1971 were those used by Hoffmann, Jones, and Genoways (1971) in 1970.

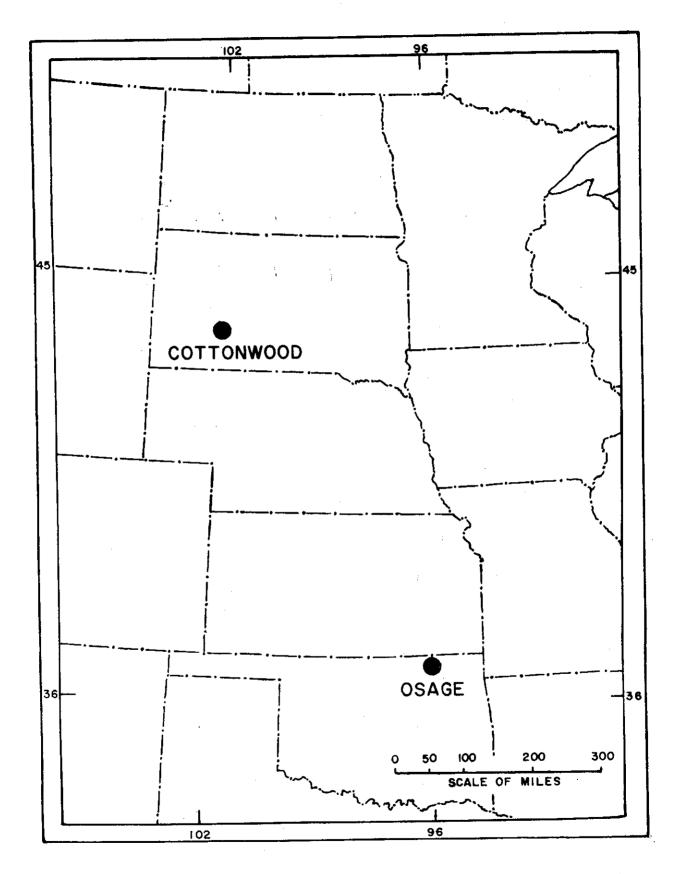

Fig. 1. Map of northern Great Plains showing location of the two IBP sites included in this report.

Trapping

Two aluminum Sherman live traps were placed at each station on the live trap grids, baited with a mixture of oatmeal and peanut butter, and set for 5 consecutive days unless rainy weather interfered, in which case a night was skipped. Traps were set in the late afternoon (usually between 1700 and 1900) each day. They were checked early in the morning (usually between 0600 and 0700), and all were sprung at that time.

Additionally, animals were kill-trapped in museum special snap traps

(Animal Trap Company) from areas well removed from live trap grids. The specimens were autopsied for evaluation of diet and reproductive activity of the populations.

Data Types

Four data types were recorded on small mammals from our grids. Examples of data sheets are included with this report (Appendix II).

Information from the live trap grids was recorded on a "vertebrate--live-trapping" data sheet. Recorded on this sheet were the generic and specific identity of the animal and its condition in the trap (normal, torpid, escaped, or dead). All small mammals were marked by toe clipping, and the code number of each was recorded. Four toes were used on each foot for clipping, starting with the right hind foot. The relative age (juvenile, subadult, or adult) and reproductive condition (females--inactive, cornified, or vulva turgid, or pregnant or lactating; males--non-breeding, questionably breeding, or breeding) of each specimen were recorded. If an animal was found to be molting, the state of molt was noted. Finally, the grid location where the specimen was captured was recorded.

For each animal from off-grid snaptrapping and any dead animals from the live trap grid, additional information was recorded on two data sheets--'mammal collection' and 'mammal reproductive.' The mammal collection sheet had information on grid location of capture, generic and specific identity, field collector's number, external measurements, stage of molt, and type of specimen prepared. Saved from most specimens were ectoparasites and stomachs for analysis of contents. On the 'mammal reproductive' sheets, reproductive condition and relative age were noted as for the livetrapped animals. In addition, for males the length and width of the testes and the condition of the epididymus and seminal vesicles were noted. The condition of the mammary glands and pubic symphysis were recorded for females. During autopsy the following information was obtained: number and size of embryos, number of embryos being resorbed, number of old and new scars, number of corpora lutea, presence or absence of corpora albicantia, and weight of the reproductive tract if it contained embryos.

Other Censusing Methods

Jackrabbits, deer, and carnivores were censused at night by spotlighting a 50-yard strip on one side of a slowly moving vehicle. All mammals observed in a minimum of 10 miles and a maximum of 40 miles at each site during each of the three collection periods were recorded. The width of the census strip was estimated, and the error of estimate was determined by measuring the distance to an object estimated to be 50 yards distant after each mile traversed.

Pocket gophers (*Thomomys talpoides*) were present only at Cottonwood. They were censused by counts of mounds and by trapping with Macabee gopher traps.

Disturbance of the habitat resulting from the activities of mammals was estimated at both sites. A series of ten 1-m sq quadrats was selected at random (by lottery) on the grids for study. Each quadrat was outlined with string and carefully searched to determine the number of runways, burrows, and mounds, and the area affected by these and other disturbances. At Cottonwood the total area on the grid disturbed by gopher mounds was measured during each collection period.

For additional discussions of methods used in small mammal sampling, see French (1971) and Hoffmann et al. (1971).

Statistical Techniques

Whenever possible, the Jolly stochastic procedure (Jolly, 1965) was used to estimate population size on the live trap grid as recommended by French (1971). However, when the assumptions of these procedures could not be met and no population could be obtained, the Zippin method (Zippin, 1956) was applied to the live trap data.

All weights were adjusted by subtraction of stomach weight and weight of reproductive tracts of pregnant females from total body weight. To convert wet body weight to dry body weight, the wet weight was multiplied by 0.3. The conversion of wet to dry weight is based upon results obtained by Golley (1960) for *Microtus pennsylvanicus*.

STUDY AREAS

The Comprehensive Network Sites visited by field teams from the University of Kansas and the University of Minnesota included Osage and Cottonwood. These sites are discussed briefly below. Information is presented on the types of

grids used, the location of the grids, the vegetation on the grids, and the general climate and topography of the area.

0sage

The Osage Site is located on the K. S. Adams Ranch 12 miles north and 5 miles east of Shidler, Osage County, Oklahoma. Both live trap and snap trap grids were studied at this site. The live trap grid was located in an ungrazed pasture just to the west of the ranch headquarters. Rows 11 and 12 were located in an area that was cultivated 12 years ago, but has not been worked since; the successional vegetation in this area was considerably different from the tallgrass on the remainder of the grid, having a dense, tall growth of forbs.

To the north and west of the grid are roads, which are bounded by moderately-grazed pastures. About 150 m south of the grid is a shelterbelt and about 250 m beyond this is a small lake. There appeared to be little or no slope on the live trap grid.

The average January temperature at Osage is 36.9°F, and the average July temperature is 81.8°F. The average annual precipitation is 36.6 inches with 25.0 inches received from April to September.

This area of northeastern Oklahoma is characterized by tallgrass prairie in uncultivated upland areas and deciduous trees along the canyons and streams. Common grasses (Risser, 1970) in the pasture where the grids were placed included big bluestem (Andropogon gerardi), little bluestem (A. scoparius), switchgrass panic (Panicum virgatum), Scribner panic (P. scribnarianum), side oats grama (Bouteloua curtipendula), blue grama (B. gracilis), yellow Indian grass (Sorghastrum nutans), tall dropseed (Sporobolus asper), and common fall witchgrass (Leptoloma cognatum). Forbs in the area were heath aster

(Aster ericoides), plains wild indigo (Baptisia leucophaea), dotted gayfeather (Liatris punctata), and white prairie clover (Petalostemum candidum).

Cottonwood

The grid at the Cottonwood Site was located on the Cottonwood Range Field Station, which is 2 miles east of Cottonwood, Jackson County, South Dakota. It was placed in summer pasture 3, which has been lightly grazed since 1942. The grid had both north- and south-facing slopes, which met toward the center of the grid and then drained toward the west. Cottonwood Creek and a small dam and reservoir were about ½ mile to the northwest of the grid. The average annual temperature on the station is about 47°F, the average daily temperature being 32.5°F in January and 90.8°F in July. The average annual rainfall at the station is 15.22 inches, May (2.78 inches) and June (2.99 inches) being the wettest months.

Under good range conditions, the vegetation of the field station is dominated by midgrasses, especially western wheatgrass (Agropyron smithii) and green needlegrass (Stipa viridula) with an understory of shortgrasses, mainly consisting of blue grama (Bouteloua gracilis) and buffalo grass (Buchloe dactyloides). Several forbs are conspicuous during the early part of the year. For additional information on plants of the Cottonwood Site, see Lewis (1970).

RESULTS

0sage--1970

During 1970 the prairie vole (*Microtus ochrogaster*) was the dominant small mammal at Osage. The population density of this vole appeared to be most strongly correlated with standing dead plant biomass.

The cotton rat (Sigmodon hispidus) was a potentially important contributor to small mammal standing crop density and biomass, but was restricted to a small area on the grid. Blarina brevicauda and Reithrodontomys montanus were captured on the grids in low numbers.

Peromyscus maniculatus and Peromyscus leucopus were restricted to the snap trap grid. Only P. maniculatus and Reithrodontomys montanus were trapped in the grazed pastures at Osage.

The best estimate of liveweight biomass of small mammals during 1970 at Osage was 1591.4 g/ha during the first trapping period and 1121.7 g/ha during the second trapping period. See Hoffmann et al. (1971) for additional details.

0sage--1971

Small mammals collected on the live trap grid at the Osage Site during the three 1971 sampling periods included Blarina brevicauda, Reithrodontomys montanus, Sigmodon hispidus, Microtus ochrogaster, Peromyscus maniculatus, Peromyscus leucopus, Mus musculus, Perognathus hispidus, and Cryptotis parva.

Other mammals taken or observed in the general vicinity of the site were Lepus californicus, Sylvilagus floridanus, Canis latraus, and Neotoma floridana.

The most striking feature of small mammal populations at Osage 1971 is the increase of biomass density from the May trapping period (when it was extremely low) to October trapping period (Fig. 2). The prairie vole (Microtus ochrogaster) and the cotton rat (Sigmodon hispidus) were the codominant small mammals on the site during the last two trapping periods (Fig. 3).

The biomass density of Blarina brevicauda, Cryptotis parva, and Peromyscus maniculatus increased during the summer as indicated by results of the third

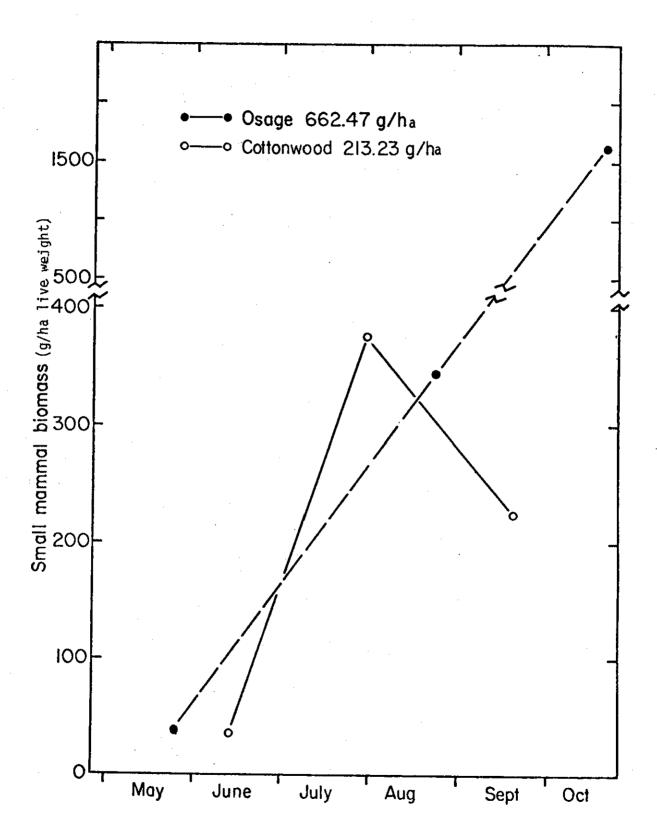

Fig. 2. Graph showing small mammal biomass (g live weight/ha) for three sampling periods on the Osage and Cottonwood Sites, 1971.

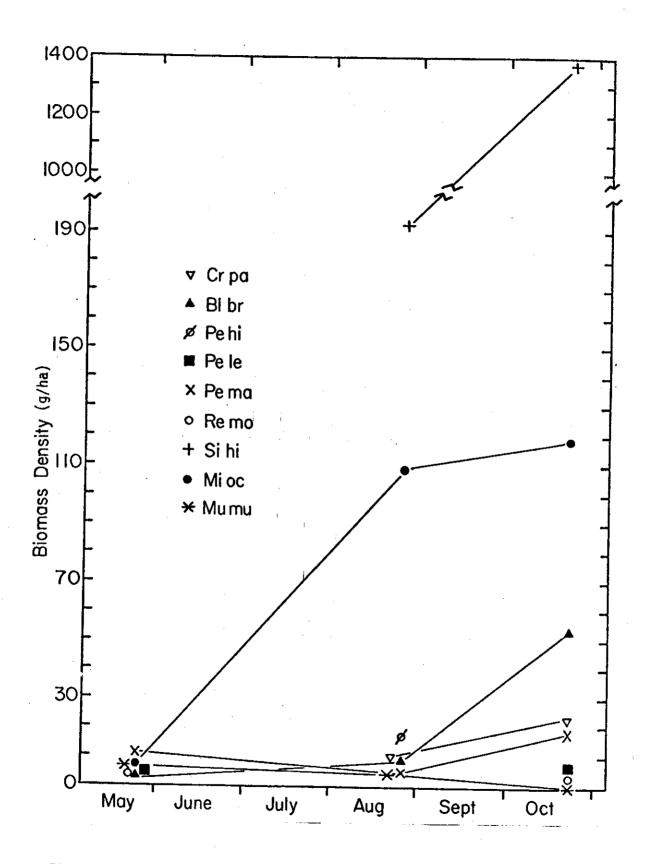

Fig. 3. Graph showing biomass density (g/ha) for each species of small mammal captured on the live trap grid at the Osage Site, 1971.

trapping period. Both *Peromyscus maniculatus* and *Peromyscus elucopus* were found on the live trap grid in contrast to the 1970 trapping when they were found only on the snap trap grid (Fig. 3).

Estimates of total numbers of small mammals on the live trap grid and of biomass densities are given in Tables 1 through 3.

Summary

Our best estimate of the liveweight biomass of small mammals at Osage is 38.51 g/ha during the first trapping period, 348.93 g/ha during the second trapping period, and 1599.89 g/ha during the third period.

Survey of Small Mammal Disturbance

Eight of the ten 1 m^2 quadrats studied in May showed signs of small mammal activity. These included six old inactive runways, one old active runway, one fresh runway, one nest, and one pile of vegetation cuttings. The total area disturbed was $0.60~\mathrm{m}^2$. Runways, mostly old and inactive, covering a combined area of $0.87~\mathrm{m}^2$ were measured in eight of 10 quadrats in August. In October, runways were observed in only two of 10 quadrats, and burrows were measured in two others. Total area disturbed was $0.30~\mathrm{m}^2$.

Jackrabbit Census

Roadside counts conducted after sunset between 2000 and 2400 resulted in the sighting of black-tailed jackrabbits (Lepus californicus), eastern cottontails (Sylvilagus floridanus), and coyotes (Canus latrans) in the vicinity of the Osage Site. Seven jackrabbits, four cottontails, and one coyote were sighted in 30.5 miles of transect in May; 12 jackrabbits and four cottontails were sighted in 39 miles in August; and two jackrabbits, one cottontail, and one coyote were seen during 20 miles of driving in October.

a/ Value from 1970 data.

Cottonwood--1970

Four species of small mammals were captured on the live trap grid in 1970. These were Spermophilus tridecemlineatus, Peromyscus leucopus,

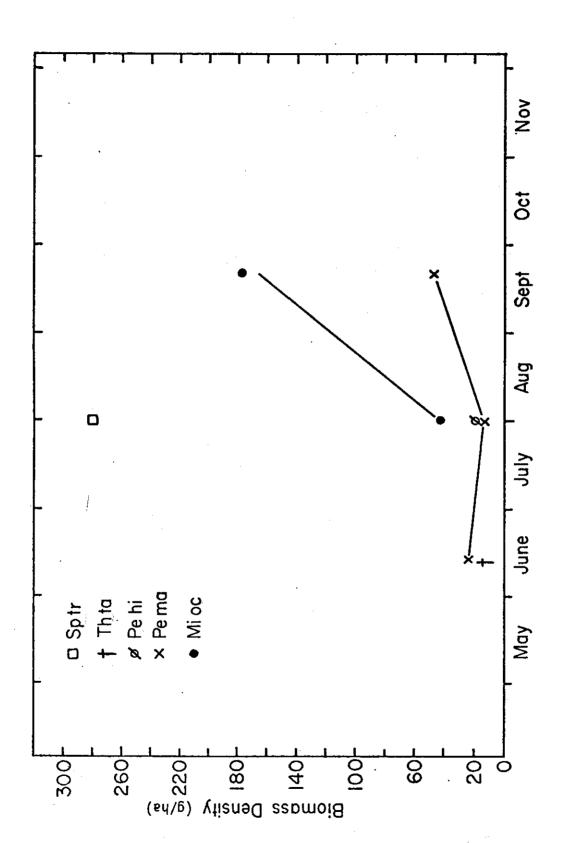

P. maniculatus, and Microtus ochrogaster. P. maniculatus was the dominant species, M. ochrogaster was present but scarce, and S. tridecemlineatus and P. leucopus were only transient on the grid. Biomass estimates of small mammals were 114.8 g/ha during June and 181.2 g/ha during August (Hoffmann et al., 1971).

Cottonwood--1971

Small mammals captured on the live trap grid at the Cottonwood Site during the three sampling periods included Spermophilus tridecemlineatus, Perognathus hispidus, Peromyscus maniculatus, Microtus ochrogaster and Thomomys talpoides. Off-grid trapping yielded specimens of all of the above in addition to specimens of Peromyscus leucopus, Reithrodontomys megalotis, Mus musculus, Microtus pennsylvanicus, and Onychomys leucogaster. One road-killed Sylvilagus floridanus and one Mustela vison found floating in a farm pond were prepared as specimens, and one Cynomys ludovicianus was collected several miles west of the site. Other mammals observed at or near the site were Lepus townsendii, Odocoileus hemionus (see below), and Ondatra zibethicus.

The small mammal biomass density at Cottonwood was extremely low during the first trapping period (June), and highest during the second trapping period (July, 379.99 g/ha). During the third trapping period (September) the biomass density dropped slightly (Fig. 2).

During the second trapping period the thirteen-lined ground squirrel was the dominant small mammal on the live trap grid, although it was completely absent during the first and third periods (Fig. 4). *Microtus ochrogaster*

Graph showing biomass density (g/ha) for each species of small mammal captured on the live trap grid at the Cottonwood Site, 1971. Fig. 4.

was dominant in September and second in importance during the second trapping period. *Peromyscus maniculatus* was dominant during the first trapping period and second in importance during the third trapping period. Estimates of total numbers and biomass densities are given in Tables 4 through 6.

Off-grid collections in the vicinity of the Cottonwood Site showed consistently higher densities of small mammal populations than are indicated by the live trap estimates. This inconsistency probably resulted from the fact that the live trap grid is situated in a grazed pasture having scanty cover, whereas most of the off-grid trapping was conducted in less heavily-grazed areas having more vegetative cover. When grazed pastures were included in off-grid trapping, there probably existed a bias toward placing traps in areas of densest vegetation or in areas inhabited by substantial populations of *Peromyscus maniculatus*.

Summary

Our best estimate of the biomass of small mammals at Cottonwood during the first trapping period is 37.88 g/ha, 379.39 g/ha during the second trapping period, and 225.87 g/ha during the third trapping period.

Small Mammal Excavation Survey

Surveys to quantify disturbance to the habitat by small mammals at Cottonwood were of two types. In June, twenty 1 m² sample quadrats were selected, but none showed evidence of disturbance. Only 10 sample plots were viewed in July, and one small burrow and one *Microtus* runway were measured. No disturbance was seen within 10 quadrats in September.

Because a species of pocket gopher (*Thomomys talpoides*) is fairly common on the grid, and gopher mounds were seen on the grid at all collecting periods,

it was obvious that the above technique was not giving a valid estimate of disturbance. Therefore, each gopher mound on the grid was measured to the nearest centimeter at the points of greatest and least diameter; these two values were averaged to compute an estimated diameter, and the area was calculated as though the mound were a circle. Twenty-four mounds (mostly old), having a total area of 11.42 m^2 , were observed in June; 36 mounds (ca. one-half new), having a total area of 29.28 m² were measured in July; and 56 mounds (mostly new), having a total area of 26.55 m^2 , were present in September. By September most of the mounds recorded as "old" in June and July were absent or only barely perceptible under vegetation and thus were not measured. The area had received considerable rainfall only a few days before the September sampling date; and gophers were extremely active pushing up mounds of wet dirt, but most of these were small. Although no Microtus runways were detected by the random quadrat method in September, several active runways were observed on the grid while gopher mounds were being measured.

Jackrabbit Census

Roadside lagomorph censuses were conducted after sunset between the hours of 1945 and 2340. Twenty-six miles of transect in June resulted in sightings of 13 Lepus townsendii, 1 Sylvilagus sp., and an unrecorded number of Odocoileus hemionus. Only two Lepus townsendii and an unrecorded number of mule deer were sighted during 30 miles of transect in July. One Jackrabbit and nine mule deer were sighted in 18 miles of transect in September.

DISCUSSION

Population density has long been known to undergo dramatic fluctuations in at least some microtines. Although not entirely regular, these fluctuations have been termed "cycles" and have been the subject of much research (e.g., Krebs, 1970). The population of *Microtus ochrogaster* at Osage apparently was near the peak density of the cycle when first trapped in May 1970 (Hoffmann et al., 1971). The number of prairie voles on the live trap grid decreased slightly in 1970 between May and August, but had crashed by May 1971. Voles were still scarce in August 1971, but the population was beginning to recover by October (Fig. 3).

We anticipate that the vole population will be high again during 1972.

The increase phase of a vole cycle is frequently characterized by winter breeding. Reproductive activity was high at Osage in October 1971, and the species has successfully bred at Lawrence, Kansas, throughout the autumn and early winter of 1971-72 (to mid-February; Robert K. Rose, personal communication).

During 1970, when vole populations were dense, only three other species of small mammals were detected on the live trap grid. Reithrodontomys montanus, Sigmodon hispidus, and Blarina brevicauda were present in low numbers at both sampling periods. All were relatively uncommon and Sigmodon was restricted in its activities on the grid to one corner characterized by mixed grasses and weedy forbs.

In 1971 when *Microtus* numbers were low, the species listed above plus five additional species (*Cryptotois parva*, *Perognathus hispidus*, *Mus musculus*, *Peromyscus maniculatus*, and *P. leucopus*) were captured on the grid (Fig. 3). The number of *S. hispidus* appreciably increased, and individual cotton rats were captured more or less randomly over the live trap grid. It will be of interest to compare the relative densities of *Sigmodon* and *Microtus* in 1972,

since both species "cycle" (Krebs, Keller, and Tamarin, 1969; Haines, 1971) and the two probably compete for at least some environmental resources (Fleharty and Olson, 1969).

Because the live trap grid at Cottonwood is grazed by livestock and thus does not provide much cover, the population of *Microtus ochrogaster* there will probably not attain densities comparable to that observed on the ungrazed grid at Osage in 1970. A total of only five *M. ochrogaster* were captured on the live trap grid at Cottonwood during both sampling periods in 1970, and none were taken in June of 1971; but by September they were the dominant species there (Fig. 3). Off-grid trapping at Cottonwood revealed high populations of reproductively-active *Microtus ochrogaster* and *M. pennsylvanicus* in September 1971. Perhaps populations of *M. ochrogaster* at Cottonwood are also in the increase phase of the cycle. It is not anticipated that *M. pennsylvanicus* will be taken on the relatively dry live trap grid even though the species is common in more mesic habitats in the immediate area.

The relative abundance of Spermophilus tridecemlineatus at Cottonwood in July was surprising, since no ground squirrels were captured or observed on the grid in June. This can be explained partially by the preponderance of young squirrels captured in July. These probably had not yet emerged from their natal burrows in June, as one female obtained from off-grid trapping was lactating. No ground squirrels were observed at the site in September, probably because most or all were in hibernation.

Studies of small mammal disturbance at both sites demonstrated a noticeable lag between the time of actual activities and the time when the activities cease to have an obvious effect on the ecosystem. At Osage some runways remained visible as late as August 1971. Because density of *Microtus* was low at that time and had been low at least since May, it is probable that

these were made in the previous summer or autumn prior to the population crash. Even so, they clearly had an effect on vegetation during the 1971 growing season.

Gopher mounds at Cottonwood represent a similar instance wherein the activity of small mammals in one year affects primary productivity at least a year later. New and old gopher mounds observed in June 1971 were roughly equal in number. Old mounds were those erected in 1970, but not yet covered with vegetation.

Density estimates of mammals too large to be captured in the Sherman live traps probably are unreliable. For example, the number of lagomorphs appear from the data to have decreased at both sites during the summer of 1971. Although this may be true, we consider it unlikely. Roadside counts are probably not accurate because roads and road ditches influence the movements of rabbits to some unknown extent. Additionally, growth of roadside and pasture vegetation during the growing season may result in sufficient cover for rabbits to be passed unnoticed. Two transects conducted at the same site on consecutive nights frequently resulted in quite different numbers of lagomorph sightings. For example, 19 miles of transect at Osage on 16 August and 17 August resulted in no sighting of Lepus californicus and only one sighting of Sylvilagus floridanus, but 9 miles of transect on 18 August produced sighting of seven L. californicus and three S. floridanus.

We believe that the density and biomass estimates of small mammals (those trappable in Sherman traps) at the Osage and Cottonwood Sites are probably reliable (Table 7). Estimates of other undomesticated mammals are probably unreliable, but will possibly have relative meaning on a year-to-year basis. Because the live trap grid at Osage is in an ungrazed pasture whereas that

at Cottonwood is in a grazed pasture, there is little comparability between the two sites as regards live trapping. Nevertheless, interesting demographic pictures are emerging from both sites. Off-grid trapping at both sites in grazed and ungrazed habitats serves as a rough index for purposes of comparison and as a measure of control concerning interpretations of data from the grids.

FIELD DATA

Live Trap Grid Data

Small mammal live trap grid data collected in 1971 at the Cottonwood and Osage Sites are Grassland Biome data sets A2U10B4 and A2U10B9. Data were collected on form NREL-10. A sample data form and an example of the data follow.

Small Mammal Collection Data

Small mammal collection data collected in 1971 at the Cottonwood and Osage Sites are Grassland Biome data sets A2U1024 and A2U1029. Data were collected on forms NREL-12A and NREL-14. Samples of these forms and an example of the data follow.
